C++ References, Const, Classes

CSE 333 Spring 2018

Instructor: Justin Hsia

Teaching Assistants:

Danny Allen	Dennis Shao	Eddie Huang
Kevin Bi	Jack Xu	Matthew Neldam
Michael Poulain	Renshu Gu	Robby Marver
Waylon Huang	Wei Lin	

Administrivia

- Exercise 8 released today, due Wednesday
  - First C++ exercise!
  - Some parallels to ex0 – compare user input checking between C/C++
- Homework 2 due next Thursday (4/26)
  - File system crawler, indexer, and search engine
  - Note: `libhw1.a` (yours or ours) needs to be in right directory
  - Demo: use Ctrl-D to exit `searchshell`, test on directory of small self-made files

Lecture Outline

- **C++ References**
- `const` in C++
- C++ Classes Intro

Pointers Reminder

Note: Arrow points to *next* instruction.

- A **pointer** is a variable containing an address
  - Modifying the pointer *doesn't* modify what it points to, but you can access/modify what it points to by *dereferencing*
  - These work the same in C and C++

```
int main(int argc, char** argv) {
  int x = 5, y = 10;
  int* z = &x;

  *z += 1;
   x += 1;

   z = &y;
  *z += 1;

  return EXIT_SUCCESS;
}
```

reference.cc

Pass-By-Reference

Note: Arrow points to *next* instruction.

- C++ allows you to truly pass-by-*reference*
  - Client passes in an argument with normal syntax
    - Function uses reference parameters with normal syntax
    - Modifying a reference parameter modifies the caller's argument!

```
void swap(int& x, int& y) {
  int tmp = x;
  x = y;
  y = tmp;
}

int main(int argc, char** argv) {
  int a = 5, b = 10;

  swap(a, b);
  cout << "a: " << a << "; b: " << b << endl;
  return EXIT_SUCCESS;
}
```

aliases that are bound to arguments

passbyreference.cc

Lecture Outline

- C++ References
- **`const` in C++**
- C++ Classes Intro

const

- const: this cannot be changed/mutated
  - Used *much* more in C++ than in C
  - Signal of intent to compiler; meaningless at hardware level
    - Results in compile-time errors

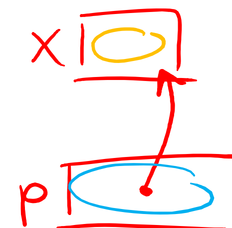
```
void BrokenPrintSquare(const int& i) {
  i = i*i;  // compiler error here!
  std::cout << i << std::endl;
}

int main(int argc, char** argv) {
  int j = 2;
  BrokenPrintSquare(j);
  return EXIT_SUCCESS;
}
```

brokenpassbyrefconst.cc

`const` and Pointers

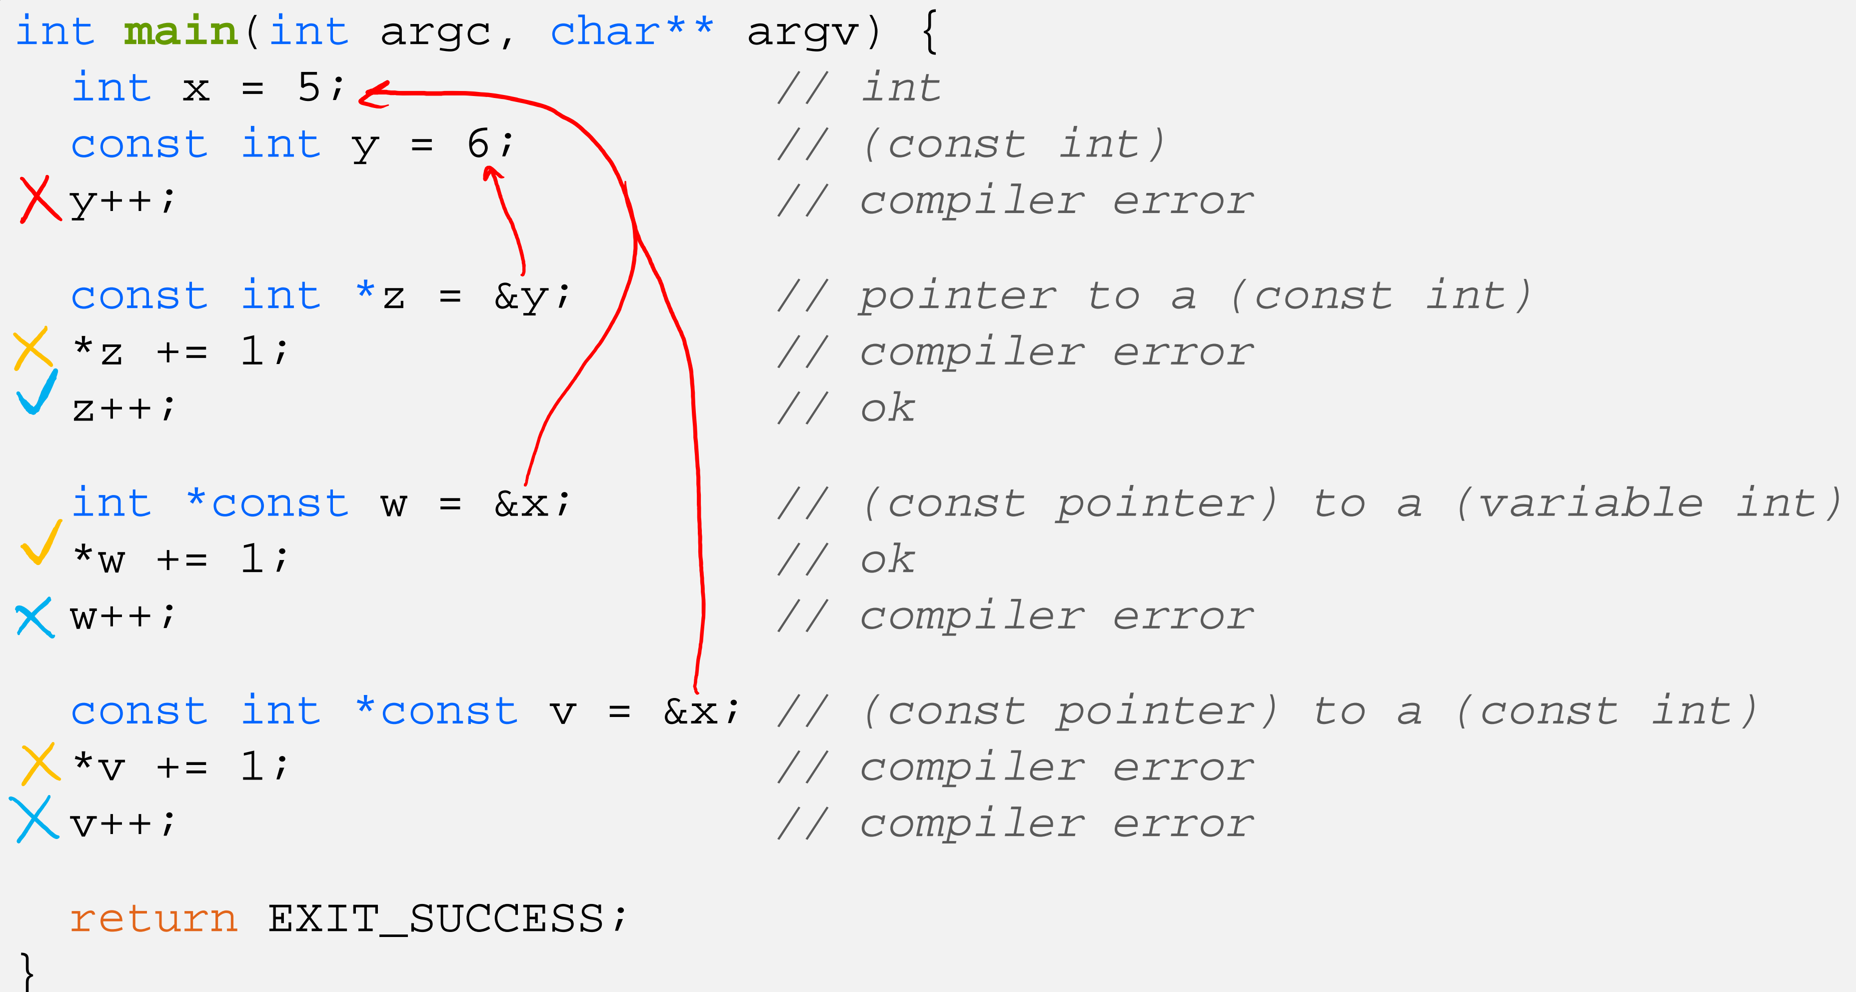
- Pointers can change data in two different contexts:
  1) You can change the value of the pointer
  2) You can change the thing the pointer points to (via dereference)



- `const` can be used to prevent either/both of these behaviors!
  - `const` next to pointer name means you can't change the value of the pointer
  - `const` next to data type pointed to means you can't use this pointer to change the thing being pointed to
  - Tip: read variable declaration from *right-to-left*

const and Pointers

- The syntax with pointers is confusing:



```
int main(int argc, char** argv) {
  int x = 5;                    // int
  const int y = 6;              // (const int)
  y++;                          // compiler error

  const int *z = &y;            // pointer to a (const int)
  *z += 1;                      // compiler error
  z++;                          // ok

  int *const w = &x;            // (const pointer) to a (variable int)
  *w += 1;                      // ok
  w++;                          // compiler error

  const int *const v = &x;      // (const pointer) to a (const int)
  *v += 1;                      // compiler error
  v++;                          // compiler error

  return EXIT_SUCCESS;
}
```

constmadness.cc

const Parameters

- A `const` parameter *cannot* be mutated inside the function
  - Therefore it does not matter if the argument can be mutated or not
- A non-`const` parameter *may* be mutated inside the function
  - It would be BAD if you passed it a `const` variable

```
void foo(const int* y) {
  std::cout << *y << std::endl;
}

void bar(int* y) {
  std::cout << *y << std::endl;
}

int main(int argc, char** argv) {
  const int a = 10;
  int b = 20;

  foo(&a);    // OK
  foo(&b);    // OK
  bar(&a);    // not OK
  bar(&b);    // OK

  return EXIT_SUCCESS;
}
```

doesn't actually modify value of y!

Peer Instruction Question

- What will happen when we try to compile and run?
  - Vote at http://PollEv.com/justinh

A. Output "(2, 4, 0)"

B. Output "(2, 4, 3)"

C. Compiler error about arguments to foo (in main)

D. Compiler error about body of foo

E. We're lost…

```
#include <iostream>

void foo(int* const x,      // can't change x, but can change what it points to
         int& y, int z) {   // int ref; local copy of int
  *x += 1;  // allowed
   y *= 2;  // allowed
   z -= 3;  // allowed, but has no lasting effect
}

int main(int argc, char** argv) {
  const int a = 1;
  int b = 2, c = 3;

  foo(&a, b, c);   // ✗ ✓ ✓
  std::cout << "(" << a << ", " << b
   << ", " << c << ")" << std::endl;

  return 0;
}
```

Style Guide Tip

don't change in function body; allows both const & non-const arguments

avoid making copy of argument

- Use const reference parameters for input values
  - Particularly for large values (no copying)
- Use pointers for output parameters
  - order: Input parameters first, then output parameters last

```
void CalcArea(const int& width, const int& height,
              int* const area) {
  *area = width * height;
}

int main(int argc, char** argv) {
  int w = 10, h = 20, a;
  CalcArea(w, h, &a);
  return EXIT_SUCCESS;
}
```

output parameter unnecessary for this example, but used for illustration

styleguide.cc

When to Use References?

- A stylistic choice, not mandated by the C++ language
- Google C++ style guide suggests:
  - Input parameters:
    - Either use values (for primitive types like `int` or small structs/objects)
    - Or use `const` references (for complex struct/object instances)
  - Output parameters:
    - Use `const` pointers
      - Unchangeable pointers referencing changeable data

Lecture Outline

- C++ References
- `const` in C++
- **C++ Classes Intro**

Classes

- Class definition syntax:

```
class Name {
 public:
  // public member definitions & declarations go here

 private:
  // private member definitions & declarations go here
};  // class Name
```

don't forget!

  - Members can be functions (methods) or data (variables)

- Class member function definition syntax:

```
retType Name::MethodName(type1 param1, …, typeN paramN) {
  // body statements
}
```

  - (1) *define* within the class definition or (2) *declare* within the class definition and then *define* elsewhere

Class Organization

- It's a little more complex than in C when modularizing with `struct` definition:
  - Class definition is part of interface and should go in `.h` file
    - Private members still must be included in definition (!)
  - In the interest of hiding details, usually separate member function definitions into companion `.cc` file
    - Common exception: setter and getter methods
  - These files can also include non-member functions that use the class

- Unlike Java, you can name files anything you want
  - Typically `Name.cc` and `Name.h` for `class Name`

Class Definition (.h file)

Point.h

```
#ifndef _POINT_H_
#define _POINT_H_

class Point {
 public:
  Point(const int x, const int y);           // constructor
  int get_x() const { return x_; }           // inline member function
  int get_y() const { return y_; }           // inline member function
  double Distance(const Point& p) const;     // member function
  void SetLocation(const int x, const int y); // member function

 private:
  int x_;  // data member
  int y_;  // data member
};  // class Point

#endif  // _POINT_H_
```

this const means that this function is not allowed to change the object on which it is called (the implicit "this" pointer)

function definitions

declarations

compiler may choose to expand inline (like a macro) instead of an actual function call

naming convention for class data members (Google C++ style guide)

Class Member Definitions (.cc file)

Point.cc

```
#include <cmath>
#include "Point.h"

Point::Point(const int x, const int y) {
  x_ = x;
  this->y_ = y;  // "this->" is optional unless name conflicts
}

double Point::Distance(const Point& p) const {
  // We can access p's x_ and y_ variables either through the
  // get_x(), get_y() accessor functions or the x_, y_ private
  // member variables directly, since we're in a member
  // function of the same class.
  double distance = (x_ - p.get_x()) * (x_ - p.get_x());
  distance += (y_ - p.y_) * (y_ - p.y_);
  return sqrt(distance);
}

void Point::SetLocation(const int x, const int y) {
  x_ = x;
  y_ = y;
}
```

BAD STYLE used here on purpose

equivalent to y_ = y;

"this" is a (Point * const)

makes "this" a (const Point * const)

equivalent to p.x_

can't be const because we are mutating "this"

Class Usage (.cc file)

usepoint.cc

```
#include <iostream>
#include "Point.h"

using namespace std;

int main(int argc, char** argv) {
  Point p1(1, 2);  // allocate a new Point on the Stack
  Point p2(4, 6);  // allocate a new Point on the Stack

  cout << "p1 is: (" << p1.get_x() << ", ";
  cout << p1.get_y() << ")" << endl;

  cout << "p2 is: (" << p2.get_x() << ", ";
  cout << p2.get_y() << ")" << endl;

  cout << "dist : " << p1.Distance(p2) << endl;
  return 0;
}
```

calls defined constructor

"dot notation" used for member functions

Reading Assignment

- Before next class, read the sections in *C++ Primer* covering class constructors, copy constructors, assignment (`operator=`), and destructors
  - Ignore "move semantics" for now
  - The table of contents and index are your friends…

Extra Exercise #1

- Write a C++ program that:
  - Has a class representing a 3-dimensional point
  - Has the following methods:
    - Return the inner product of two 3D points
    - Return the distance between two 3D points
    - Accessors and mutators for the `x`, `y`, and `z` coordinates

Extra Exercise #2

- Write a C++ program that:
  - Has a class representing a 3-dimensional box
    - Use your Extra Exercise #1 class to store the coordinates of the vertices that define the box
    - Assume the box has right-angles only and its faces are parallel to the axes, so you only need 2 vertices to define it
  - Has the following methods:
    - Test if one box is inside another box
    - Return the volume of a box
    - Handles <<, =, and a copy constructor
    - Uses `const` in all the right places
