C++ STL, Smart Pointers Intro
CSE 333 Spring 2018

Instructor: Justin Hsia

Teaching Assistants:
Danny Allen    Dennis Shao    Eddie Huang
Kevin Bi       Jack Xu        Matthew Neldam
Michael Poulain Renshu Gu    Robby Marver
Waylon Huang   Wei Lin
**Administrivia**

- Exercise 12 released today, due Monday

- Midterm is next Friday (5/4) @ 5–6 pm in GUG 220
  - 1 double-sided page of handwritten notes; *(subject to change)*
    reference sheet provided on exam
  - **Topics:** everything from lecture, exercises, project, etc. up through hw2 and C++ **templates**
  - Old exams on course website, review in section next week
Lecture Outline

❖ STL (finish)
  ▪ List
  ▪ Map

❖ Smart Pointers Intro
STL list

- A generic doubly-linked list
  - Elements are not stored in contiguous memory locations
    - Does not support random access (e.g. cannot do `list[5]`)
  - Some operations are much more efficient than vectors
    - Constant time insertion, deletion anywhere in list
    - Can iterate forward or backwards
  - Has a built-in sort member function
    - Doesn’t copy! Manipulates list structure instead of element values
#include <list>
#include <algorithm>
#include "Tracer.h"
using namespace std;

void PrintOut(const Tracer& p) {
    cout << " printout: " << p << endl;
}

int main(int argc, char** argv) {
    Tracer a, b, c;
    list<Tracer> lst;

    lst.push_back(c);
    lst.push_back(a);
    lst.push_back(b);
    cout << "sort:" << endl;
    lst.sort();
    cout << "done sort!" << endl;
    for_each(lst.begin(), lst.end(), &PrintOut);
    return 0;
}
STL **map**

- One of C++'s *associative* containers: a key/value table, implemented as a tree
  - General form: `map<key_type, value_type> name;`
  - Keys must be *unique*
    - `multimap` allows duplicate keys
  - Efficient lookup (O(log n)) and insertion (O(log n))
    - Access value via `name[key]`
  - Elements are of type `pair<key_type, value_type>` and are stored in *sorted* order
    - Key type must support less-than operator (`<`)
    - If iterating over map elements, key is field `first`, value is field `second`
map Example

```cpp
void PrintOut(const pair<Tracer,Tracer>& p) {
    cout << "printout: [" << p.first << "," << p.second << "]" << endl;
}

int main(int argc, char** argv) {
    Tracer a, b, c, d, e, f;
    map<Tracer,Tracer> table;
    map<Tracer,Tracer>::iterator it;

    table.insert(pair<Tracer,Tracer>(a, b));
    table[c] = d;
    table[e] = f;
    cout << "table[e]:" << table[e] << endl;
    it = table.find(c);

    cout << "PrintOut(*it), where it = table.find(c)" << endl;
    PrintOut(*it);

    cout << "iterating:" << endl;
    for_each(table.begin(), table.end(), &PrintOut);

    return 0;
}
```

Basic map Usage

- animals.cc
Homegrown `pair<>`
Unordered Containers (C++11)

- unordered_map, unordered_set
  - And related classes unordered_multimap, unordered_multiset
  - Average case for key access is O(1)
    - But range iterators can be less efficient than ordered map/set
  - See C++ Primer, online references for details
Lecture Outline

- STL (finish)
  - List
  - Map
- Smart Pointers Intro
Motivation

- We noticed that STL was doing an enormous amount of copying

- One solution: store pointers in containers instead of objects
  - But who’s responsible for deleting and when???
A smart pointer is an object that stores a pointer to a heap-allocated object

- A smart pointer looks and behaves like a regular C++ pointer
  - By overloading *, ->, [], etc.
- These can help you manage memory
  - The smart pointer will delete the pointed-to object at the right time (timing depends on what kind of smart pointer), including invoking the object’s destructor
  - With correct use of smart pointers, you no longer have to remember when to delete new’d memory!
A Toy Smart Pointer

- We can implement a simple one with:
  - A constructor that accepts a pointer
  - A destructor that frees the pointer
  - Overloaded * and -> operators that access the pointer
ToyPtr Class Template

```cpp
#ifndef _TOYPTR_H_
#define _TOYPTR_H_

template <typename T> class ToyPtr {
public:
    ToyPtr(T *ptr) : ptr_(ptr) { }  // constructor
    ~ToyPtr() { }  // destructor
    if (ptr_ != nullptr) {
        delete ptr_;  
        ptr_ = nullptr;
    }

    T &operator*() { return *ptr_; }  // * operator
    T *operator->() { return ptr_; }  // -> operator

private:
    T *ptr_;  // the pointer itself
};

#endif  // _TOYPTR_H_
```
ToyPtr Example

```cpp
#include <iostream>
#include "ToyPtr.h"

// simply struct to use
typedef struct { int x = 1, y = 2; } Point;
std::ostream &operator<<(std::ostream &out, const Point &rhs) {
    return out << "(" << rhs.x << "," << rhs.y << ")";
}

int main(int argc, char **argv) {
    // Create a dumb pointer
    Point *leak = new Point;

    // Create a "smart" pointer (OK, it's still pretty dumb)
    ToyPtr<Point> notleak(new Point);

    std::cout << " *leak: " << *leak << std::endl;
    std::cout << " leak->x: " << leak->x << std::endl;
    std::cout << " *notleak: " << *notleak << std::endl;
    std::cout << " notleak->x: " << notleak->x << std::endl;
    return 0;
}
```
What Makes This a Toy?

- Can’t handle:
  - Arrays
  - Copying
  - Reassignment
  - Comparison
  - ... plus many other subtleties...

- Luckily, others have built non-toy smart pointers!
  - More next lecture!
Extra Exercise #1

- Take one of the books from HW2's `test_tree` and:
  - Read in the book, split it into words (you can use your hw2)
  - For each word, insert the word into an STL `map`
    - The key is the word, the value is an integer
    - The value should keep track of how many times you've seen the word, so each time you encounter the word, increment its map element
    - Thus, build a histogram of word count
  - Print out the histogram in order, sorted by word count
  - **Bonus**: Plot the histogram on a log-log scale (use Excel, gnuplot, etc.)
    - x-axis: log(word number), y-axis: log(word count)
Extra Exercise #2

- Implement `Triple`, a class template that contains three “things,” i.e. it should behave like `std::pair` but hold 3 objects instead of 2
  - The “things” can be of different types

- Write a program that:
  - Instantiates several `Triples` that contain `ToyPtr<int>`s
  - Insert the `Triples` into a `vector`
  - Reverse the `vector`
  - Doesn’t have any memory errors (use Valgrind!)
  - **Note:** You will need to update `ToyPtr.h` — how?
