Client-side Networking
CSE 333 Spring 2018

Instructor: Justin Hsia

Teaching Assistants:
Danny Allen    Dennis Shao    Eddie Huang
Kevin Bi       Jack Xu       Matthew Neldam
Michael Poulain Renshu Gu    Robby Marver
Waylon Huang    Wei Lin
Adminstrivia

- hw3 is due Thursday (5/17)
  - Usual reminders: don’t forget to tag, clone elsewhere, and recompile

- Exercise 15 will be released on Thursday
  - Related to section this week

- hw4 out on Friday (5/18)
Socket API: Client TCP Connection

- There are five steps:
  1) Figure out the IP address and port to connect to
  2) Create a socket
  3) Connect the socket to the remote server
  4) `read()` and `write()` data using the socket
  5) Close the socket
DNS Lookup Example

- See `dnsresresolve.cc`

```c
struct addrinfo {
    int    ai_flags;       // additional flags
    int    ai_family;      // AF_INET, AF_INET6, AF_UNSPEC
    int    ai_socktype;    // SOCK_STREAM, SOCK_DGRAM, 0
    int    ai_protocol;    // IPPROTO_TCP, IPPROTO_UDP, 0
    size_t ai_addrlen;     // length of socket addr in bytes
    struct sockaddr* ai_addr; // pointer to socket addr
    char*   ai_canonname;  // canonical name
    struct addrinfo* ai_next; // can form a linked list
};
```
Step 2: Creating a Socket

- \textbf{int socket(int domain, int type, int protocol)};

- Creating a socket doesn’t bind it to a local address or port yet
- Returns file descriptor or -1 on error

```cpp
#include <arpa/inet.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#include <iostream>

int main(int argc, char** argv) {
    int socket_fd = socket(AF_INET, SOCK_STREAM, 0);
    if (socket_fd == -1) {
        std::cerr << strerror(errno) << std::endl;
        return EXIT_FAILURE;
    }
    close(socket_fd);
    return EXIT_SUCCESS;
}
```
Step 3: Connect to the Server

- The `connect()` system call establishes a connection to a remote host
  - `int connect(int sockfd, const struct sockaddr* addr, socklen_t addrlen);`
    - `sockfd`: Socket file description from Step 2
    - `addr` and `addrlen`: Related to address structures from Step 1
    - Returns 0 on success and -1 on error

- `connect()` may take some time to return
  - It is a `blocking` call by default
  - The network stack within the OS will communicate with the remote host to establish a TCP connection to it
    - This involves ~2 `round trips` across the network
Connect Example

- See `connect.cc`

```c
// Get an appropriate sockaddr structure.
struct sockaddr_storage addr;
size_t addrlen;
LookupName(argv[1], port, &addr, &addrlen);

// Create the socket.
int socket_fd = socket(addr.ss_family, SOCK_STREAM, 0);
if (socket_fd == -1) {
    cerr << "socket() failed: " << strerror(errno) << endl;
    return EXIT_FAILURE;
}

// Connect the socket to the remote host.
int res = connect(socket_fd,
                  reinterpret_cast<sockaddr*>(&addr),
                  addrlen);
if (res == -1) {
    cerr << "connect() failed: " << strerror(errno) << endl;
}
```
Review Question

How do we error check `read()` and `write()`?

A. `ferror()`
B. Return value less than expected
C. Return value of 0 or NULL
D. Return value of -1
E. We’re lost...
Step 4: read()

- If there is data that has already been received by the network stack, then read will return immediately with it
  - `read()` might return with less data than you asked for

- If there is no data waiting for you, by default `read()` will block until something arrives
  - This might cause deadlock!
  - Can `read()` return 0?
Step 4: read()

- Assume we have:
  - `int socket_fd; // fd of connected socket`
  - `char readbuf[BUF]; // read buffer`
  - `int res; // to store read result`

- Write C++ code to read in BUF characters from `socket_fd`
  - If error occurs, send error message to user and exit()
Step 4: **write**()

- **write**() enqueues your data in a send buffer in the OS and then returns
  - The OS transmits the data over the network in the background
  - When **write**() returns, the receiver probably has not yet received the data!

- If there is no more space left in the send buffer, by default **write**() will *block*
Read/Write Example

```c
while (1) {
    int wres = write(socket_fd, readbuf, res);
    if (wres == 0) {
        cerr << "socket closed prematurely" << endl;
        close(socket_fd);
        return EXIT_FAILURE;
    }
    if(wres == -1) {
        if (errno == EINTR)
            continue;
        cerr << "socket write failure: " << strerror(errno) << endl;
        close(socket_fd);
        return EXIT_FAILURE;
    }
    break;
}
```

- See `sendreceive.cc`
  - Demo
Step 5: `close()`

- `int close(int fd);`

  Nothing special here – it’s the same function as with file I/O
Extra Exercise #1

- Write a program that:
  - Reads DNS names, one per line, from stdin
  - Translates each name to one or more IP addresses
  - Prints out each IP address to stdout, one per line
