333 Section 10 - Concurrency and pthreads

Welcome back :)

Process

- A process has a virtual address space. Each process is started with a single thread but can create additional threads.

Threads

- A thread contains a sequential execution of a program and is contained within a process.
- Threads of the same process share a memory/address space: use the same heap, globals, and code but each thread has its own stack.

POSIX threads (pthreads) API

- Part of the standard C/C++ libraries and declared in `pthread.h`.
- **Must compile and link with** `-pthread`.

```
int pthread_create(pthread_t *thread, const pthread_attr_t *attr,
                   void *(*start_routine) (void *), void *arg);
```

➔ `thread`: Output parameter for thread identifier
➔ `attr`: Used to set thread attributes. Use `NULL` for defaults.
➔ `start_routine`: Pointer to a function that the thread will execute upon creation.
➔ `arg`: A single argument that may be passed to `start_routine`. `NULL` may be used if no argument is to be passed.
★ Creates a new thread and calls `start_routine(arg)`.
★ Returns 0 if successful and an error number otherwise.

```
int pthread_join(pthread_t thread, void **retval);
```

★ Called by parent thread to wait for the termination of the thread specified by `thread`. If `retval` is non-`NULL`, then `retval` acts an output parameter and the address passed to `pthread_exit` by the finished thread is stored in it.
★ Returns 0 if successful and an error number otherwise.

```
void pthread_exit(void *retval);
```

★ Terminates the calling thread with an optional termination status parameter, `retval`, which can just be set to `NULL`.

POSIX mutual exclusion (mutex) API

- Restrict access to sections of code in order to protect shared data from being simultaneously accessed by multiple threads.

```
int pthread_mutex_init(pthread_mutex_t *mutex,
                       const pthread_mutexattr_t *attr);
```

★ Initializes the mutex referenced by `mutex` with attributes specified by `attr` (use `NULL` for adefault ttributes).

```
int pthread_mutex_destroy(pthread_mutex_t *mutex);
```
★ Destroys (*i.e.* uninitializes) the mutex object referenced by `mutex`.

```
int pthread_mutex_lock(pthread_mutex_t *mutex);
```
★ Attempts to acquire the mutex object referenced by `mutex` and blocks if it's currently held by another thread. Should be placed at the start of your critical section of code.

```
int pthread_mutex_unlock(pthread_mutex_t *mutex);
```
★ Releases the mutex object referenced by `mutex`. Should be placed at the end of your critical section of code.

Question

Imagine we have:

```
MyClass onTheStack;
pthread_t child;
pthread_create(&child, nullptr, foo, &onTheStack);
```

`onTheStack` is on the parent thread's stack. However, each thread has its own stack!

Can we still access `onTheStack` from the child? Why or why not?

1) Consider the following multithreaded C program:

```c
int g = 0;
void *worker(void *ignore) {
  for (int k = 1; k <= 3; k++) {
    g = g + k;
  }
  printf("g = %d\n", g);
  return NULL;
}

int main() {
  pthread_t t1, t2;
  int ignore;
  ignore = pthread_create(&t1, NULL, &worker, NULL);
  ignore = pthread_create(&t2, NULL, &worker, NULL);
  pthread_join(t1, NULL);
  pthread_join(t2, NULL);
  return EXIT_SUCCESS;
}
```

Give three different possible outputs (there are many)

What are the possible final values of the global variable ‘g’? (circle all possible)

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15+

2) Calculating primes is slow. In C++, use 10 threads to calculate the primes less than 1,000. Then, print them out in ascending order:

```
#define NTHREAD 10
struct Bounds {
  int lo;
  int hi;
  Bounds(int lo, int hi): lo(lo), hi(hi) {}
};

bool isPrime(int num) { … }

Void *getPrimes(void *data) {
  Bounds *b = reinterpret_cast<Bounds*>(data);
  // setup a way to store the primes we find in order

  // calculate primes

  // ???
  return
}
```

// continued on next page

```
int main() {
  // make space to store our threads and data
  std::vector<std::unique_ptr<Bounds>> bounds;

  // create and run our threads
  int err;
  for (int i = 0; i < NTHREAD; i++) {

  }

  // wait for each thread to finish and get its data
  for (int i = 0; i < NTHREAD; i++) {
    // wait for thread, storing its return value

    // print the data

  }

  return 0;
}
```

3) It's the payday! It's time for UW to pay each of the 333 TAs their monthly salary. Each of the TA's bank account is inside the `bank_accounts[]` array and the person who is in charged of paying the TAs is a 333 student and decided to use pthreads to pay the TAs by adding 1000 into each bank account. Here is the program the student wrote:

```
// Assume all necessary libraries and header files are included
const int NUM_TAS = 10;

static int bank_accounts[NUM_TAS];
static pthread_mutex_t sum_lock;

void *thread_main(void *arg) {
  int *TA_index = reinterpret_cast<int*>(arg);

  pthread_mutex_lock(&sum_lock);
  bank_accounts[*TA_index] += 1000;
  pthread_mutex_unlock(&sum_lock);

  delete TA_index;
  return NULL;
}

int main(int argc, char** argv) {
  pthread_t thds[NUM_TAS];
  pthread_mutex_init(&sum_lock, NULL);

  for (int i = 0; i < NUM_TAS; i++) {
    int *num = new int(i);
    if (pthread_create(&thds[i], NULL, &thread_main, num) != 0) {
      /*report error*/
    }
  }

  for (int i = 0; i < NUM_TAS; i++) {
    cout << bank_accounts[i] << endl;

  }

  pthread_mutex_destroy(&sum_lock);
  return 0;
}
```

(see next page)

a) Does the program increase the TAs' bank accounts correctly? Why or why not?

b) Could we implement this program using processes instead of threads? Why would or why wouldn't we want to do this?

c) Assume that all the problems, if any, are now fixed. The student discovers that the program they wrote is kinda slow even though its a multithreaded program. Why might it be the case? And how would you fix that?

4)

a) List some reasons why it's better to use multiple threads within the same process rather than multiple processes running the same program

b) What benefits could there be to using multiple processes instead of multiple threads?

c) Which registers will for sure be different between two threads that are executing different functions?

d) How does the OS distinguish the threads?
