Memory and Arrays
CSE 333 Spring 2019

Instructor: Justin Hsia

Teaching Assistants:
Aaron Johnston    Andrew Hu    Daniel Snitkovskiy
Forrest Timour    Kevin Bi      Kory Watson
Pat Kosakanchit   Renshu Gu     Tarkan Al-Kazily
Travis McGaha
Administrivia

- Pre-Course Survey & Mini-Bio due tomorrow night

- Exercise 0 was due this morning
  - Solutions will be posted this afternoon
  - Grades back early next week – reference system is the CSE Linux environment
  - If you haven’t been added to Gradescope yet, email your ex0 submission to Justin ASAP

- Exercise 1 out today and due Friday morning @ 11 am

- Homework 0 released today
  - Logistics and infrastructure for homework
  - Set up GitLab (and VM) before section – bring laptop if any issues
    - Using the 19wi CSE VM this quarter
Lecture Outline

- C’s Memory Model (refresher)
- Pointers (refresher)
- Arrays
OS and Processes

- The OS lets you run multiple applications at once
  - An application runs within an OS “process”
  - The OS time slices each CPU between runnable processes
    - This happens very quickly: ~100 times per second

![Diagram of processes and operating system]

**Operating System**

Process 1  Process 2  ...  Process N
Processes and Virtual Memory

- The OS gives each process the illusion of its own private memory
  - Called the process’ address space
  - Contains the process’ virtual memory, visible only to it (via translation)
  - \(2^{64}\) bytes on a 64-bit machine

Virtual Memory

- Contains code, data, libraries, stack, etc.
Loading

- When the OS loads a program it:
  1) Creates an address space
  2) Inspects the executable file to see what’s in it
  3) (Lazily) copies regions of the file into the right place in the address space
  4) Does any final linking, relocation, or other needed preparation

![Diagram of memory regions]

0xFF...FF

OS kernel [protected]

Stack

Shared Libraries

Heap

Read/Write Segment
  .data, .bss

Read-Only Segment
  .text, .rodata

0x00...00
Memory Management

- **Local variables on the Stack**
  - Allocated and freed via calling conventions (push, pop, mov)

- **Global and static variables in Data**
  - Allocated/freed when the process starts/exits

- **Dynamically-allocated data on the Heap**
  - `malloc()` to request; `free()` to free, otherwise memory leak

Diagram:
- OS kernel [protected]
- Stack
- Shared Libraries
- Heap
- Static Data
- Literals
- Instructions
- OxFF...FF
- Ox00...00
Review: The Stack

- Used to store data associated with function calls
  - Compiler-inserted code manages stack frames for you

- Stack frame (x86-64) includes:
  - Address to return to
  - Saved registers
    - Based on calling conventions
  - Local variables
  - Argument build
    - Only if > 6 used
Stack in Action

```c
#include <stdint.h>

int f(int, int); // function declarations because functions defined below where they are first used in file
int g(int);

int main(int argc, char** argv) {
    int n1 = f(3, -5);
    n1 = g(n1);
}

int f(int p1, int p2) {
    int x;
    int a[3];
    ...
    x = g(a[2]);
    return x;
}

int g(int param) {
    return param * 2;
}
```

Note: arrow points to next instruction to be executed (like in `gdb`).
Stack in Action

```
#include <stdint.h>

int f(int, int);
int g(int);

int main(int argc, char** argv) {
  int n1 = f(3,-5);
  n1 = g(n1);
}

int f(int p1, int p2) {
  int x;
  int a[3];
  ...
  x = g(a[2]);
  return x;
}

int g(int param) {
  return param * 2;
}
```

Note: arrow points to next instruction to be executed (like in gdb).
Stack in Action

#include <stdint.h>

int f(int, int);
int g(int);

int main(int argc, char** argv) {
    int n1 = f(3, -5);
    n1 = g(n1);
}

int f(int p1, int p2) {
    int x;
    int a[3];
    ...
    x = g(a[2]);
    return x;
}

int g(int param) {
    return param * 2;
}
# Stack in Action

```
#include <stdint.h>

int f(int, int);
int g(int);

int main(int argc, char** argv) {
    int n1 = f(3, -5);
    n1 = g(n1);
}

int f(int p1, int p2) {
    int x;
    int a[3];
    ...
    x = g(a[2]);
    return x;
}

int g(int param) {
    return param * 2;
}
```

Note: arrow points to next instruction to be executed (like in gdb).
Lecture Outline

- C’s Memory Model (refresher)
- **Pointers** (refresher)
- Arrays
Pointers

- Variables that store addresses
  - It points to somewhere in the process’ virtual address space
  - `&foo` produces the virtual address of `foo`

- Generic definition: `type* name;` or `type *name;`
  - Recommended: do not define multiple pointers on the same line: `int *p1, p2;` is not the same as `int *p1, *p2;`
  - Instead, use: `int *p1; int *p2;`

- Dereference a pointer using the unary `*` operator
  - Access the memory referred to by a pointer
#include <stdio.h>
#include <stdint.h>

int main(int argc, char** argv) {
    int x = 351;
    int* p;    // p is a pointer to a int

    p = &x;    // p now contains the addr of x
    printf("&x is %p\n", &x);
    printf(" p is %p\n", p);
    printf(" x is %d\n", x);

    *p = 333;   // change the value of x
    printf(" x is %d\n", x);

    return 0;
}
Something Curious

What happens if we run `pointy.c` several times?

```
bash$ gcc -Wall -std=c11 -o pointy pointy.c
bash$ ./pointy
&x is 0x7fff8524
p is 0x7ffff9e28524
x is 351
x is 333
bash$ ./pointy
&x is 0x7fff847be34
p is 0x7fffe847be34
x is 351
x is 333
bash$ ./pointy
&x is 0x7fff87b14644
p is 0x7fffe7b14644
x is 351
x is 333
bash$ ./pointy
&x is 0x7fff80dfe54
p is 0x7ffff0dfe54
x is 351
x is 333
```
Address Space Layout Randomization

- Linux uses *address space layout randomization* (ASLR) for added security
  - Randomizes:
    - Base of stack
    - Shared library (mmap) location
  - Makes Stack-based buffer overflow attacks tougher
  - Makes debugging tougher
  - Can be disabled (*gdb* does this by default); Google if curious

![Diagram of OS kernel and address space layout]
Lecture Outline

- C’s Memory Model (refresher)
- Pointers (refresher)
- Arrays
Arrays

Definition: `type name[size]`
- Allocates `size*sizeof(type)` bytes of contiguous memory
- Normal usage is a compile-time constant for `size` (e.g. `int scores[175];`)
- Initially, array values are “garbage”

Size of an array
- Not stored anywhere – array does not know its own size!
  - `sizeof(array)` only works in variable scope of array definition
- Recent versions of C (but not C++) allow for variable-length arrays
  - Uncommon and can be considered bad practice [we won’t use]

```c
int n = 175;
int scores[n];  // OK in C99
```
Challenge Question

- The code snippets both use a variable-length array. What will happen when we compile with C99?

```c
int m = 175;
int scores[m];

void foo(int n) {
    ...
}
```

```c
int m = 175;
void foo(int n) {
    int scores[n];
    ...
}
```

A. Compiler Error
B. Compiler Error
C. No Error
D. No Error
E. We’re lost...
Using Arrays

- **Initialization:**
  
  ```
  type name[size] = {val0,...,valN};
  ```

  - `{ }` initialization can only be used at time of definition
  - If no `size` supplied, infers from length of array initializer

- Array name used as identifier for “collection of data”
  
  - `name[index]` specifies an element of the array and can be used as an assignment target or as a value in an expression
  
  - Array name (by itself) produces the address of the start of the array
    
    - Cannot be assigned to / changed

```
int primes[6] = {2, 3, 5, 6, 11, 13};
primes[3] = 7;
primes[100] = 0; // memory smash! (hope for segfault)
```
Multi-dimensional Arrays

- **Generic 2D format:**
  
  ```c
  type name[rows][cols] = {{values},...,{values}};
  ```
  
  - Still allocates a single, contiguous chunk of memory
  - C is **row-major**

```c
// a 2-row, 3-column array of doubles
double grid[2][3];

// a 3-row, 5-column array of ints
int matrix[3][5] = {
  {0, 1, 2, 3, 4},
  {0, 2, 4, 6, 8},
  {1, 3, 5, 7, 9}
};
```
Parameters: reference vs. value

- There are two fundamental parameter-passing schemes in programming languages
  - Call-by-value/“Pass-by-value”
    - Parameter is a local variable initialized with a copy of the calling argument when the function is called; manipulating the parameter only changes the copy, \textit{not} the calling argument
    - C, Java, C++ (most things)
  - Call-by-reference/“Pass-by-reference”
    - Parameter is an alias for the supplied argument; manipulating the parameter manipulates the calling argument
    - C++ references (we’ll see more later)
Arrays as Parameters

- It’s tricky to use arrays as parameters
  - What happens when you use an array name as an argument?
  - Arrays do not know their own size

```c
int sumAll(int a[]); // prototype

int main(int argc, char** argv) {
    int numbers[] = {9, 8, 1, 9, 5};
    int sum = sumAll(numbers);
    return 0;
}

int sumAll(int a[]) {
    int i, sum = 0;
    for (i = 0; i < ...???
}
Solution 1: Declare Array Size

```c
int sumAll(int a[5]); // prototype

int main(int argc, char** argv) {
    int numbers[] = {9, 8, 1, 9, 5};
    int sum = sumAll(numbers);
    printf("sum is: %d\n", sum);
    return 0;
}

int sumAll(int a[5]) {
    int i, sum = 0;
    for (i = 0; i < 5; i++) {
        sum += a[i];
    }
    return sum;
}
```

- Problem: loss of generality/flexibility
Solution 2: Pass Size as Parameter

```c
int sumAll(int a[], int size); // prototype

int main(int argc, char** argv) {
    int numbers[] = {9, 8, 1, 9, 5};
    int sum = sumAll(numbers, 5);
    printf("sum is: %d\n", sum);
    return 0;
}

int sumAll(int a[], int size) {
    int i, sum = 0;
    for (i = 0; i < size; i++) {
        sum += a[i];
    }
    return sum;
}
```

arraysum.c

- This is the standard idiom in C programs
Returning an Array

- Local variables, including arrays, are allocated on the Stack
  - They “disappear” when a function returns!
  - Can’t safely return local arrays from functions
    - Can’t return an array as a return value – why not?

```c
int* copyArray(int src[], int size) {
    int i, dst[size];  // OK in C99

    for (i = 0; i < size; i++) {
        dst[i] = src[i];
    }

    return dst;  // no compiler error, but wrong!
}
```

`buggy_copyarray.c`
Solution: Output Parameter

- Create the “returned” array in the caller
  - Pass it as an output parameter to `copyarray()`
    - A pointer parameter that allows the called function to store values that the caller can use
  - Works because arrays are “passed” as pointers
    - “Feels” like call-by-reference, but technically it’s not

```c
void copyArray(int src[], int dst[], int size) {
    int i;
    for (i = 0; i < size; i++) {
        dst[i] = src[i];
    }
}
```

copyarray.c
Arrays: Call-By-Value or Call-By-Reference?

- **Technical answer:** a \( \text{T} \ [ ] \) array parameter is “promoted” to a pointer of type \( \text{T}^* \), and the *pointer* is passed by value
  - So it acts like a call-by-reference array (if callee changes the array parameter elements it changes the caller’s array)
  - But it’s really a call-by-value pointer (the callee can change the pointer parameter to point to something else(!))

```c
void copyArray(int src[], int dst[], int size) {
    int i;
    dst = src;
    for (i = 0; i < size; i++) {
        dst[i] = src[i]; // copies source array to itself!
    }
}
```
Output Parameters

- Output parameters are common in library functions
  - `long int strtol(char* str, char** endptr, int base);`
  - `int sscanf(char* str, char* format, ...);`

```c
int num, i;
char *pEnd, *str1 = "333 rocks";
char str2[10];

// converts "333 rocks" into long -- pEnd is conversion end
num = (int) strtol(str1, &pEnd, 10);

// reads string into arguments based on format string
num = sscanf("3 blind mice", "%d %s", &i, str2);
```

```c
outparam.c
```
Extra Exercises

- Some lectures contain “Extra Exercise” slides
  - Extra practice for you to do on your own without the pressure of being graded
  - You may use libraries and helper functions as needed
    - Early ones may require reviewing 351 material or looking at documentation for things we haven’t reviewed in 333 yet
  - Always good to provide test cases in `main()`

- Solutions for these exercises will be posted on the course website
  - You will get the most benefit from implementing your own solution before looking at the provided one
Extra Exercise #1

- Write a function that:
  - Accepts an array of 32-bit unsigned integers and a length
  - Reverses the elements of the array in place
  - Returns nothing (`void`)
Extra Exercise #2

- Write a function that:
  - Accepts a string as a parameter
  - Returns:
    - The first white-space separated word in the string as a newly-allocated string
    - AND the size of that word
