Client-side Networking CSE 333 Winter 2019

Instructor: Hal Perkins

Teaching Assistants:

Alexey Beall Renshu Gu Harshita Neti

David Porter Forrest Timour Soumya Vasisht

Yifan Xu Sujie Zhou

Administrivia

- HW3 due Thursday night
- Exercise 13 (smart pointers) due Monday
- Exercise 15 due Monday released after sections Thursday
 - Client-side TCP connection
- Companion exercise 16 out end of week, due next
 Wednesday
 - Server-side TCP connection (to talk with your client-side code!)

Socket API: Client TCP Connection

- There are five steps:
 - 1) Figure out the IP address and port to connect to
 - 2) Create a socket
 - 3) Connect the socket to the remote server
 - 4) read() and write() data using the socket
 - 5) Close the socket

Step 1: DNS Lookup

- Remaining details covered in section this week
- * See dnsresolve.cc

Step 2: Creating a Socket

```
int socket(int domain, int type, int protocol);
```

- Creating a socket doesn't bind it to a local address or port yet
- Returns file descriptor or -1 on error

socket.cc

```
#include <arpa/inet.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#include <iostream>
int main(int argc, char** argv) {
  int socket fd = socket (AF INET, SOCK STREAM, 0);
  if (socket fd == -1) {
     std::cerr << strerror(errno) << std::endl;</pre>
     return EXIT FAILURE;
  close(socket fd);
  return EXIT SUCCESS;
```

Step 3: Connect to the Server

- The connect() system call establishes a connection to a remote host
 - - sockfd: Socket file description from Step 2
 - addr and addrlen: Usually from one of the address structures returned by getaddrinfo in Step 1 (DNS lookup)
 - Returns 0 on success and -1 on error
- connect() may take some time to return
 - It is a blocking call by default
 - The network stack within the OS will communicate with the remote host to establish a TCP connection to it
 - This involves ~2 round trips across the network

Connect Example

* See connect.cc

```
// Get an appropriate sockaddr structure.
struct sockaddr storage addr;
size t addrlen;
LookupName (arqv[1], port, &addr, &addrlen);
// Create the socket.
int socket fd = socket(addr.ss family, SOCK STREAM, 0);
if (socket fd == -1) {
  cerr << "socket() failed: " << strerror(errno) << endl;</pre>
 return EXIT FAILURE;
// Connect the socket to the remote host.
int res = connect(socket fd,
                   reinterpret cast<sockaddr*>(&addr),
                   addrlen);
if (res == -1) {
  cerr << "connect() failed: " << strerror(errno) << endl;</pre>
```

Step 4: read()

- If there is data that has already been received by the network stack, then read will return immediately with it
 - read () might return with less data than you asked for
- If there is no data waiting for you, by default read()
 will block until something arrives
 - This might cause deadlock!
 - Can read() return 0?

Step 4: write()

- * write() enqueues your data in a send buffer in the OS and then returns
 - The OS transmits the data over the network in the background
 - When write() returns, the receiver probably has not yet received the data!
- If there is no more space left in the send buffer, by default write () will block

Read/Write Example

```
while (1) {
  int wres = write(socket fd, readbuf, res);
  <u>if</u> (wres == 0) {
    cerr << "socket closed prematurely" << endl;</pre>
    close(socket fd);
    return EXIT FAILURE;
  if (wres == -1) {
    if (errno == EINTR)
      continue;
    cerr << "socket write failure: " << strerror(errno) << endl;</pre>
    close(socket fd);
    return EXIT FAILURE;
 break;
```

- * See sendreceive.cc
 - Demo

Step 5: close()

```
* int close(int fd);
```

- Nothing special here it's the same function as with file I/O
- Shuts down the socket and frees resources and file descriptors associated with it on both ends of the connection

Extra Exercise #1

- Write a program that:
 - Reads DNS names, one per line, from stdin
 - Translates each name to one or more IP addresses
 - Prints out each IP address to stdout, one per line
