pollev.com/cse33320su

About how long did Exercise 14 take?

- A. 0-1 Hours
- B. 1-2 Hours
- C. 2-3 Hours
- D. 3-4 Hours
- E. 4+ Hours
- F. I didn't submit / I prefer not to say

Side question:
Best way to cook a potato?

Administrivia

- ❖ Exercise 13 released today, due Monday
 - C++ smart pointers (Today's topic!)
- ❖ HW3 is due Thursday (8/6)
 - Get started if you haven't done so already!
 - Useful debugging tools covered in section, look over those materials
- ❖ Mid quarter feedback:
 - Pacing is a bit fast (partially due to only having 9 weeks, sorry!)
 - Students like polls, a bit split on breakout rooms though
 - Code examples that are posted could be better
 - Include examples with good style &

Lecture Outline

- ❖ Smart Pointers
 - Intro and toy_ptr
 - unique_ptr
 - Reference Counting and shared_ptr vs weak_ptr

Last Time...

- ❖ We learned about STL
- ❖ We noticed that STL was doing an enormous amount of copying
- ❖ If we want to store Derived objects in an STL container of Base objects, we get object slicing 😞
- ❖ A solution: store pointers in containers instead of objects
 - But who's responsible for deleting and when???

C++ Smart Pointers

- ❖ A **smart pointer** is an *object* that stores a pointer to a heap-allocated object
 - A smart pointer looks and behaves like a regular C++ pointer
 - By overloading *, ->, [], etc.
 - These can help you manage memory
 - The smart pointer will delete the pointed-to object *at the right time* including invoking the object's destructor
 - When that is depends on what kind of smart pointer you use
 - With correct use of smart pointers, you no longer have to remember when to delete new'd memory!

A Toy Smart Pointer

- ❖ We can implement a simple one with:
 - A constructor that accepts a pointer
 - A destructor that frees the pointer
 - Overloaded * and –> operators that access the pointer

A smart pointer is just a
Template object.

ToyPtr Class Template

ToyPtr.h

```
#ifndef _TOYPTR_H_
#define _TOYPTR_H_

template <typename T> class ToyPtr {
public:
    ToyPtr(T *ptr) : ptr_(ptr) {}           // constructor
    ~ToyPtr() { delete ptr_; }              // destructor

    Takes advantage of implicit calling of destructor to clean up for us
    T &operator*() { return *ptr_; }         // * operator
    T *operator->() { return ptr_; }        // -> operator

private:
    T *ptr_;                                // the pointer itself
};

#endif // _TOYPTR_H_
```

ToyPtr Example

usetoy.cc

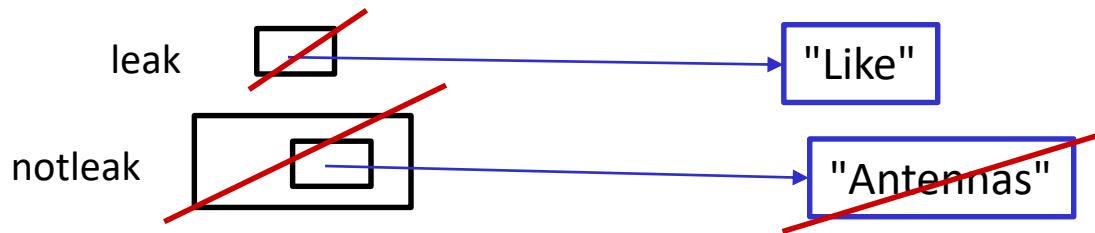

```
#include <iostream>
#include <cstdlib>
#include "ToyPtr.h"

int main(int argc, char **argv) {
    // Create a dumb pointer
    std::string *leak = new std::string("Like");

    // Create a "smart" pointer (OK, it's still pretty dumb)
    ToyPtr<std::string> notleak(new std::string("Antennas"));

    std::cout << "    *leak: " << *leak << std::endl;
    std::cout << "*notleak: " << *notleak << std::endl;

    return EXIT_SUCCESS;
}
```

Notleak cleans up for us,
leak has a memory leak

What Makes This a Toy?

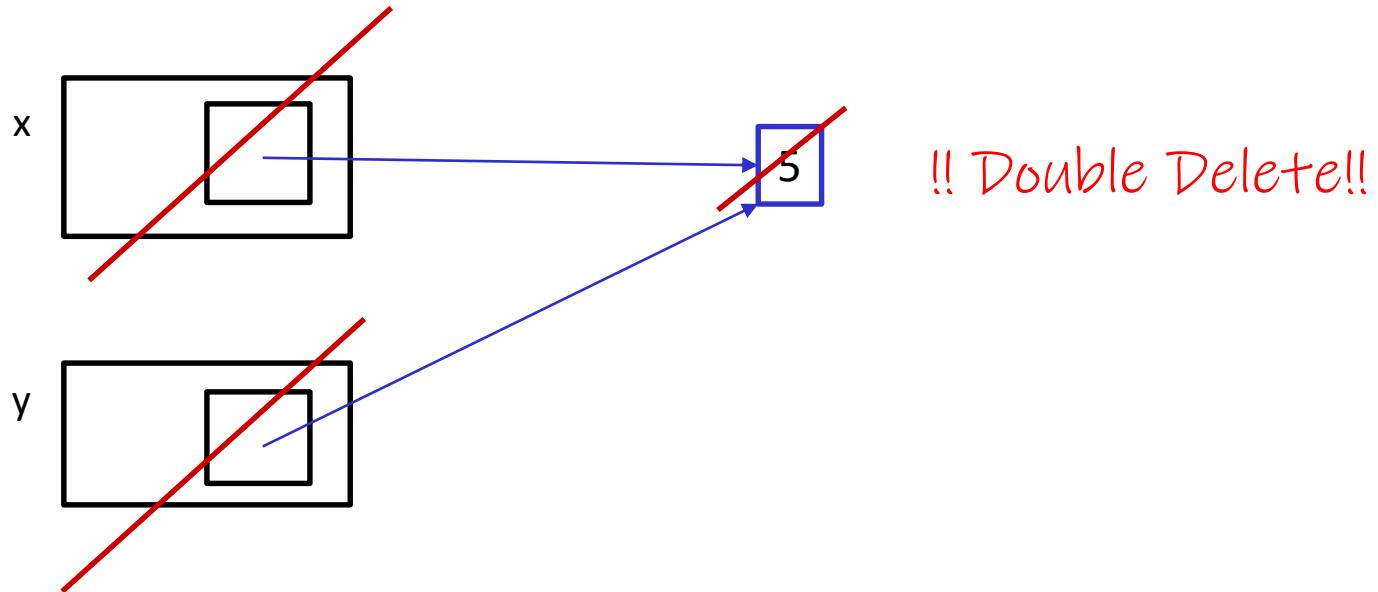

- ❖ Can't handle:
 - Arrays // needs to use `delete []`
 - Copying
 - Reassignment
 - Comparison
 - ... plus many other subtleties...
- ❖ Luckily, others have built non-toy smart pointers for us!

ToyPtr Class Template Issues

UseToyPtr.cc

```
#include "./ToyPtr.h"

// We want two pointers!
int main(int argc, char **argv) {
    ToyPtr<int> x(new int(5));
    ToyPtr<int> y = x;
    return EXIT_SUCCESS;
}
```

Lecture Outline

❖ Smart Pointers

- Intro and `toy_ptr`
- `unique_ptr`
- Reference Counting and `shared_ptr` vs `weak_ptr`

Introducing: `unique_ptr`

- ❖ A `unique_ptr` is the *sole owner* of its pointee
 - It will call `delete` on the pointee when it falls out of scope
Via the `unique_ptr` destructor
- ❖ Guarantees uniqueness by disabling copy and assignment

Using unique_ptr

Must include `<memory>`

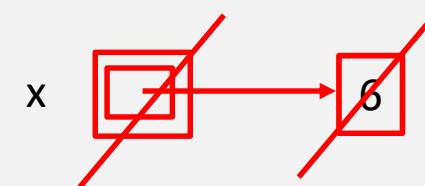

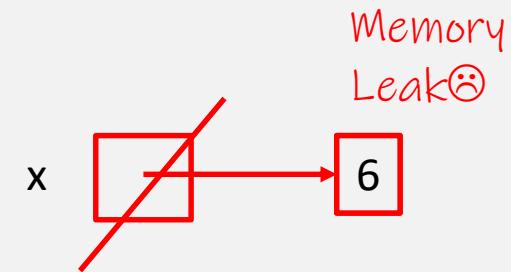

unique1.cc

```
#include <iostream>      // for std::cout, std::endl
#include <memory>        // for std::unique_ptr
#include <cstdlib>        // for EXIT_SUCCESS

void Leaky() {
    int *x = new int(5);    // heap-allocated
    (*x)++;
    std::cout << *x << std::endl;
} // never used delete, therefore leak

void NotLeaky() {
    std::unique_ptr<int> x(new int(5)); // wrapped, heap-allocated
    (*x)++;
    std::cout << *x << std::endl;
} // never used delete, but no leak

int main(int argc, char **argv) {
    Leaky();
    NotLeaky();
    return EXIT_SUCCESS;
}
```

unique_ptrs Cannot Be Copied

- ❖ `std::unique_ptr` has disabled its copy constructor and assignment operator
 - You cannot copy a `unique_ptr`, helping maintain “uniqueness” or “ownership”

uniquefail.cc

```
#include <memory>    // for std::unique_ptr
#include <cstdlib>    // for EXIT_SUCCESS

int main(int argc, char **argv) {
    std::unique_ptr<int> x(new int(5));    // ctor that takes a pointer ✓
    std::unique_ptr<int> y(x);            // cctor, disabled. compiler error ✗
    std::unique_ptr<int> z;                // default ctor, holds nullptr ✓
    z = x;                                // op=, disabled. compiler error ✗
    return EXIT_SUCCESS;
}
```

Zoom voting:

Compiles
yes

Doesn't compile
no

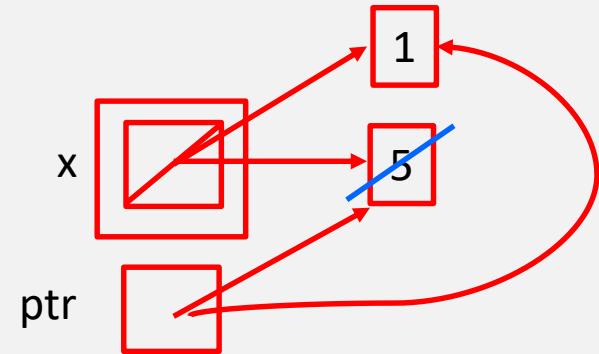

unique_ptr Operations

unique2.cc

```
#include <memory>      // for std::unique_ptr
#include <cstdlib>       // for EXIT_SUCCESS

using namespace std;
typedef struct { int a, b; } IntPair;

int main(int argc, char **argv) {
    unique_ptr<int> x(new int(5));
    int *ptr = x.get(); // Return a pointer to pointed-to object
    int val = *x;        // Return the value of pointed-to object
    // Access a field or function of a pointed-to object
    unique_ptr<IntPair> ip(new IntPair);
    ip->a = 100;
    // Deallocate current pointed-to object and store new pointer
    x.reset(new int(1));
    ptr = x.release(); // Release responsibility for freeing
    delete ptr;
    return EXIT_SUCCESS;
}
```

Transferring Ownership

- ❖ Use **reset** () and **release** () to transfer ownership
 - **release** returns the pointer, sets wrapped pointer to nullptr
 - **reset** **delete**'s the current pointer and stores a new one

```
int main(int argc, char **argv) {  
    unique_ptr<int> x(new int(5));  
    cout << "x: " << x.get() << endl;  
  
    unique_ptr<int> y(x.release()); // x abdicates ownership to y  
    cout << "x: " << x.get() << endl;  
    cout << "y: " << y.get() << endl;  
  
    unique_ptr<int> z(new int(10));  
    // y transfers ownership of its pointer to z.  
    // z's old pointer was delete'd in the process.  
    z.reset(y.release());  
  
    return EXIT_SUCCESS;  
}
```

The diagram illustrates the state of pointers x, y, and z at different stages of the program execution:

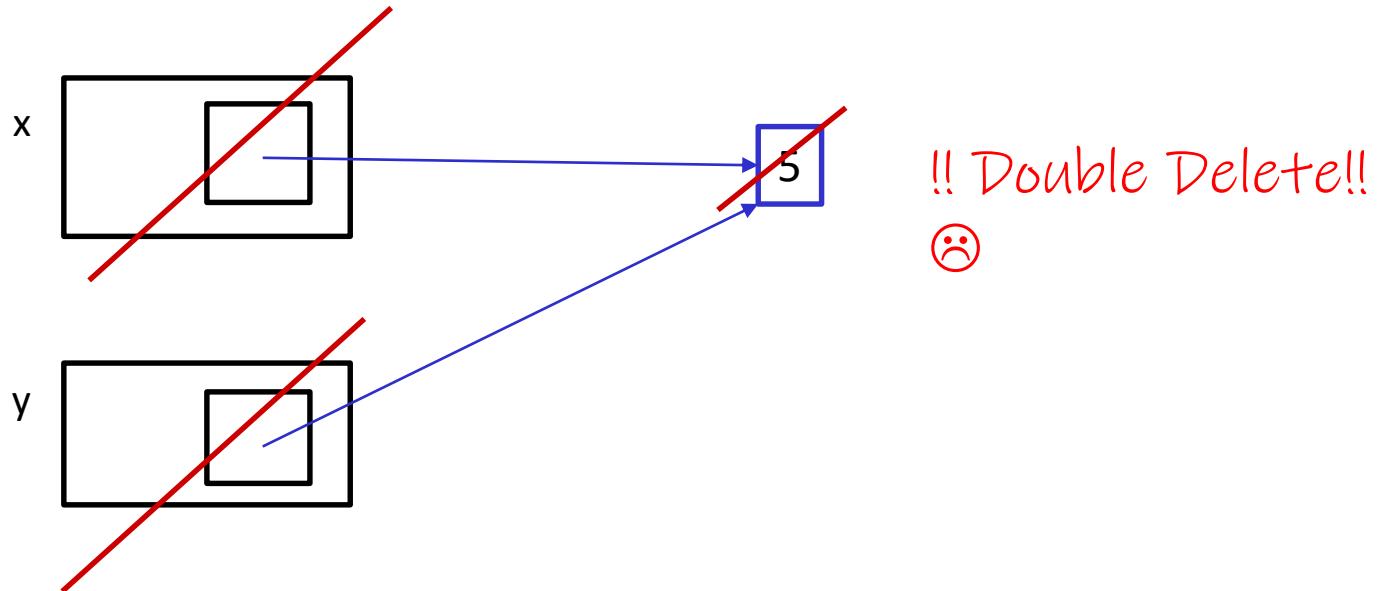

- Initial State:** x points to a heap-allocated integer containing 5. A red arrow points from x to the value 5.
- After x.release():** x is null (indicated by a crossed-out square). y points to the same heap-allocated integer containing 5. A red arrow points from y to the value 5.
- After z.reset(y.release()):** x is null. y is null. z points to a heap-allocated integer containing 10. A red arrow points from z to the value 10.

Caution with get() !!

UseToyPtr.cc

```
#include <memory>

// Trying to get two pointers to the same thing
int main(int argc, char **argv) {
    unique_ptr<int> x(new int(5));
    unique_ptr<int> y(x.get());
    return EXIT_SUCCESS;
}
```

unique_ptr and STL

- ❖ `unique_ptr`s can be stored in STL containers
 - Wait, what? STL containers like to make lots of copies of stored objects and `unique_ptr`s cannot be copied...
- ❖ Move semantics to the rescue!
 - When supported, STL containers will *move* rather than *copy*
 - `unique_ptr`s support move semantics

We will discuss move semantics
briefly, not a core concept to 333

Aside: Copy Semantics

- ❖ Assigning values typically means making a copy
 - Sometimes this is what you want
 - e.g. assigning a string to another makes a copy of its value
 - Sometimes this is wasteful
 - e.g. assigning a returned string goes through a temporary copy

```
std::string ReturnString(void) {  
    std::string x("Justin");  
    return x; // this return might copy  
}  
  
int main(int argc, char **argv) {  
    std::string a("bleg");  
    std::string b(a); // copy a into b  
  
    b = ReturnString(); // copy return value into b  
  
    return EXIT_SUCCESS;  
}
```

copysemantics.cc

Aside: Move Semantics (C++11)

- ❖ “Move semantics” move values from one object to another without copying (“stealing”)
 - Useful for optimizing away temporary copies
 - A complex topic that uses things called “*rvalue references*”
 - Mostly beyond the scope of 333 this quarter

movesemantics.cc

```
std::string ReturnString(void) {
    std::string x("Justin");
    // this return might copy
    return x;
}

int main(int argc, char **argv) {
    std::string a("bleg");

    // moves a to b
    std::string b = std::move(a);
    std::cout << "a: " << a << std::endl;
    std::cout << "b: " << b << std::endl;

    // moves the returned value into b
    b = std::move(ReturnString());
    std::cout << "b: " << b << std::endl;

    return EXIT_SUCCESS;
}
```

unique_ptr and STL Example

uniquevec.cc

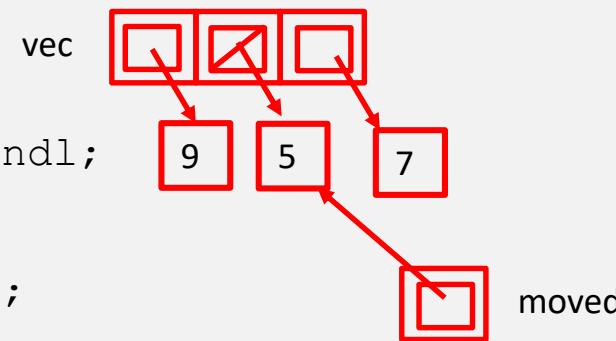

```
int main(int argc, char **argv) {
    std::vector<std::unique_ptr<int>> vec;

    vec.push_back(std::unique_ptr<int>(new int(9)));
    vec.push_back(std::unique_ptr<int>(new int(5)));
    vec.push_back(std::unique_ptr<int>(new int(7)));

    // z holds 5
    int z = *vec[1];
    std::cout << "z is: " << z << std::endl;

    // compiler error!
    std::unique_ptr<int> copied = vec[1];
    // moved points to 5, vec[1] is nullptr
    std::unique_ptr<int> moved = std::move(vec[1]);
    std::cout << "*moved: " << *moved << std::endl;
    std::cout << "vec[1].get(): " << vec[1].get() << std::endl;

    return EXIT_SUCCESS;
}
```

unique_ptr and Arrays

- ❖ `unique_ptr` can store arrays as well
 - Will call `delete []` on destruction

unique5.cc

```
#include <memory>      // for std::unique_ptr
#include <cstdlib>      // for EXIT_SUCCESS

using namespace std;

int main(int argc, char **argv) {
    unique_ptr<int[]> x(new int[5]);

    x[0] = 1;
    x[2] = 2;

    return EXIT_SUCCESS;
}
```

Lecture Outline

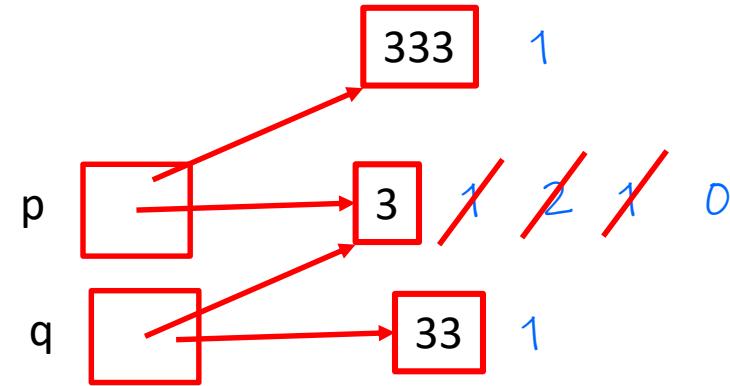

❖ Smart Pointers

- Intro and `toy_ptr`
- `unique_ptr`
- **Reference Counting and `shared_ptr` vs `weak_ptr`**

Reference Counting

- ❖ Reference counting is a technique for managing resources by counting and storing the number of references (*i.e.* pointers that hold the address) to an object

```
int *p = new int(3);  
int *q = p;  
q = new int(33);  
p = new int(333);
```

`std::shared_ptr`

- ❖ `shared_ptr` is similar to `unique_ptr` but we allow shared objects to have multiple owners
 - The copy/assign operators are not disabled and *increment* or *decrement* reference counts as needed
 - After a copy/assign, the two `shared_ptr` objects point to the same pointed-to object and the (shared) reference count is 2
 - When a `shared_ptr` is destroyed, the reference count is *decremented*
 - When the reference count hits 0, we `delete` the pointed-to object!

shared_ptr Example

sharedexample.cc

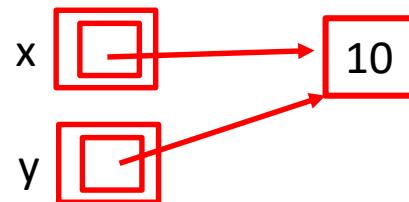

```
#include <cstdlib>      // for EXIT_SUCCESS
#include <iostream>       // for std::cout, std::endl
#include <memory>        // for std::shared_ptr

int main(int argc, char **argv) {
    std::shared_ptr<int> x(new int(10)); // ref count: 1

    // temporary inner scope (!)
    {
        std::shared_ptr<int> y = x;           // ref count: 2
        std::cout << *y << std::endl;
    }

    std::cout << *x << std::endl;          // ref count: 1

    return EXIT_SUCCESS;
}                                         // ref count: 0
```

shared_ptrs and STL Containers

- ❖ Even simpler than `unique_ptrs`
 - Safe to store `shared_ptrs` in containers, since copy/assign maintain a shared reference count

sharedvec.cc

```
vector<std::shared_ptr<int>> vec;

vec.push_back(std::shared_ptr<int>(new int(9)));
vec.push_back(std::shared_ptr<int>(new int(5)));
vec.push_back(std::shared_ptr<int>(new int(7)));

int &z = *vec[1];
std::cout << "z is: " << z << std::endl;

std::shared_ptr<int> copied = vec[1]; // works!
std::cout << "*copied: " << *copied << std::endl;

std::shared_ptr<int> moved = std::move(vec[1]); // works!
std::cout << "*moved: " << *moved << std::endl;
std::cout << "vec[1].get(): " << vec[1].get() << std::endl;
```

Cycle of shared_ptrs

strongcycle.cc

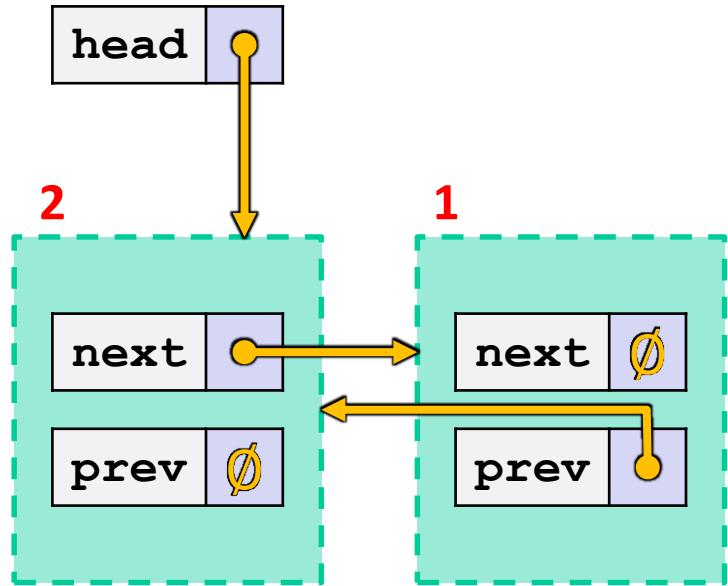

```
#include <cstdlib>
#include <memory>

using std::shared_ptr;

struct A {
    shared_ptr<A> next;
    shared_ptr<A> prev;
};

int main(int argc, char **argv) {
    shared_ptr<A> head(new A());
    head->next = shared_ptr<A>(new A());
    head->next->prev = head;

    return EXIT_SUCCESS;
}
```

- ❖ What happens when we **delete** head?

std::weak_ptr

- ❖ `weak_ptr` is similar to a `shared_ptr` but doesn't affect the reference count
 - Can *only* “point to” an object that is managed by a `shared_ptr`
 - Not *really* a pointer – can't actually dereference unless you “get” its associated `shared_ptr`
 - Because it doesn't influence the reference count, `weak_ptr`s can become “*dangling*”
 - Object referenced may have been `delete`'d
 - But you can check to see if the object still exists
- ❖ Can be used to break our cycle problem!

Breaking the Cycle with `weak_ptr`

weakcycle.cc

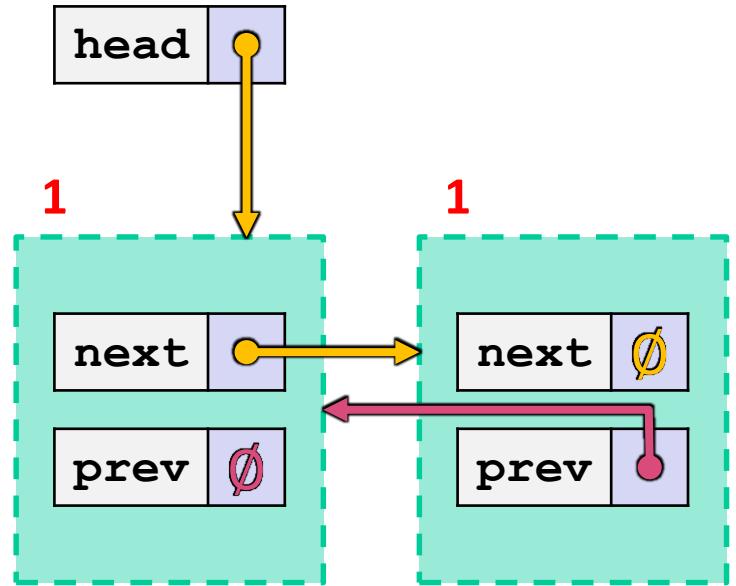

```
#include <cstdlib>
#include <memory>

using std::shared_ptr;
using std::weak_ptr;

struct A {
    shared_ptr<A> next;
    weak_ptr<A> prev;
};

int main(int argc, char **argv) {
    shared_ptr<A> head(new A());
    head->next = shared_ptr<A>(new A());
    head->next->prev = head;

    return EXIT_SUCCESS;
}
```

- ❖ Now what happens when we `delete head`?

Using a `weak_ptr`

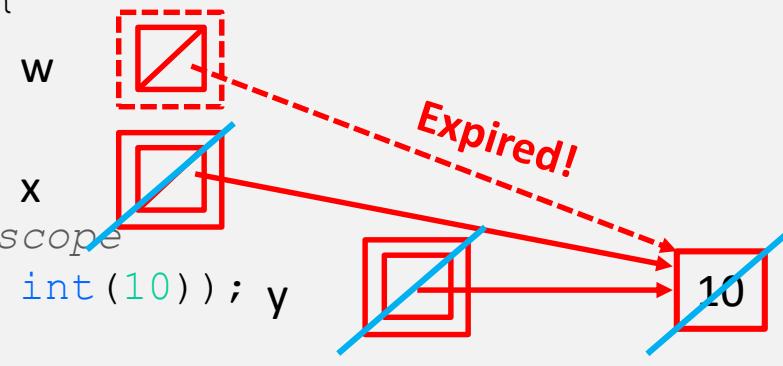

usingweak.cc

```
#include <cstdlib>      // for EXIT_SUCCESS
#include <iostream>       // for std::cout, std::endl
#include <memory>        // for std::shared_ptr, std::weak_ptr

int main(int argc, char **argv) {
    std::weak_ptr<int> w;

    { // temporary inner scope
        std::shared_ptr<int> x;
        { // temporary inner-inner scope
            std::shared_ptr<int> y(new int(10)); y
            w = y;
            x = w.lock(); // returns "promoted" shared_ptr
            std::cout << *x << std::endl;
        }
        std::cout << *x << std::endl;
    }
    std::shared_ptr<int> a = w.lock(); p2
    std::cout << a << std::endl;

    return EXIT_SUCCESS;
}
```

“Smart” Pointers

- ❖ Smart pointers still don’t know everything, you must be careful with what pointers you give it to manage.
 - Smart pointers can’t tell if a pointer is on the heap or not.
 - Still uses delete on default.
 - Smart pointers can’t tell if you are re-using a raw pointer.

Using a non-heap pointer

```
#include <cstdlib>
#include <memory>

using std::shared_ptr;
using std::weak_ptr;

int main(int argc, char **argv) {
    int x = 333;

    shared_ptr<int> p1(&x);

    return EXIT_SUCCESS;
}
```

- ❖ Smart pointers can't tell if the pointer you gave points to the heap!
 - Will still call delete on the pointer when destructed.

Re-using a raw pointer

```
#include <cstdlib>
#include <memory>

using std::unique_ptr;

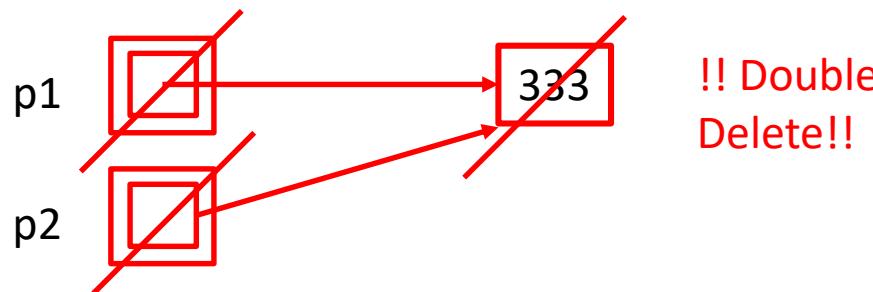

int main(int argc, char **argv) {
    int *x = new int(333);

    unique_ptr<int> p1(x);

    unique_ptr<int> p2(x);

    return EXIT_SUCCESS;
}
```

- ❖ Smart pointers can't tell if you are re-using a raw pointer.

Re-using a raw pointer

```
#include <cstdlib>
#include <memory>

using std::shared_ptr;

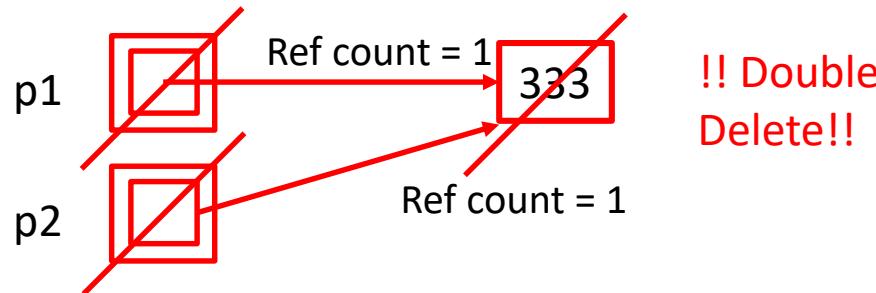

int main(int argc, char **argv) {
    int *x = new int(333);

    shared_ptr<int> p1(x); // ref count: 1

    shared_ptr<int> p2(x); // ref count: 1

    return EXIT_SUCCESS;
}
```

- ❖ Smart pointers can't tell if you are re-using a raw pointer.

Re-using a raw pointer: Fixed Code

```
#include <cstdlib>
#include <memory>

using std::shared_ptr;

int main(int argc, char **argv) {
    int *x = new int(333);

    shared_ptr<int> p1(new int(333));

    shared_ptr<int> p2(p1); // ref count:

    return EXIT_SUCCESS;
}
```

- ❖ Smart pointers can't tell if you are re-using a raw pointer.
 - Takeaway: be careful!!!!
 - Safer to use ctor
 - To be extra safe, don't have a raw pointer variable!

Lecture Summary

- ❖ A `unique_ptr` **takes ownership** of a pointer
 - Cannot be copied, but can be moved
 - `get()` returns a copy of the pointer, but is dangerous to use; better to use `release()` instead
 - `reset()` `deletes` old pointer value and stores a new one
- ❖ A `shared_ptr` allows shared objects to have multiple owners by doing *reference counting*
 - `deletes` an object once its reference count reaches zero
- ❖ A `weak_ptr` works with a shared object but doesn't affect the reference count
 - Can't actually be dereferenced, but can check if the object still exists and can get a `shared_ptr` from the `weak_ptr` if it does

Some Important Smart Pointer Methods

Visit <http://www.cplusplus.com/> for more information on these!

- ❖ `std::unique_ptr U;`
 - `U.get()` Returns the raw pointer U is managing
 - `U.release()` U stops managing its raw pointer and returns the raw pointer
 - `U.reset(q)` U cleans up its raw pointer and takes ownership of q
- ❖ `std::shared_ptr S;`
 - `S.get()` Returns the raw pointer S is managing
 - `S.use_count()` Returns the reference count
 - `S.unique()` Returns true iff S.use_count() == 1
- ❖ `std::weak_ptr W;`
 - `W.lock()` Constructs a shared pointer based off of W and returns it
 - `W.use_count()` Returns the reference count
 - `W.expired()` Returns true iff W is expired (W.use_count() == 0)
