## Sockets \& DNS CSE 333 Summer 2020

## Instructor: <br> Travis McGaha

Teaching Assistants:
Jeter Arellano Ian Hsiao

Ramya Challa
Allen Jung

Kyrie Dowling
Sylvia Wang

## How is HW3 Looking?

A. I'm done with HW3 (or working on the bonus)
B. I've started and I will probably finish on time
C. I've started but I will likely need to use at least one late day
D. I'm unsure if I will need to use lateday(s) or not
E. I do not think I can get HW3 done by the lateday deadline. (Sunday @ midnight)
F. I prefer not to say

Side question:
How do you say gif?

## Administrivia

* hw3 is due Thursday (8/6)
- Usual reminder: don't forget to tag, clone elsewhere, and recompile $* * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * *$
* $k * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * * *$
* hw4 out on Friday (8/7)
* Exercise 15 will be released on Thursday
- Related to section this week
- Can start looking at it early; we'll finish covering material on Friday

## Lecture Outline

* Network Programming
- Sockets API
- Network Addresses
- DNS Lookup

## Files and File Descriptors

* Remember open (), read (), write (), and
close()?
- POSIX system calls for interacting with files
- open () returns a file descriptor Parameters to can't be $a \rightarrow$. An integer that represents an open file
- This file descriptor is then passed to read (), write (), and
- Inside the OS, the file descriptor is used to index into a table that keeps track of any OS-level state associated with the file, such as the file position

## Networks and Sockets

* UNIX likes to make all I/O look like file I/O
- You use read () and write () to communicate with remote computers over the network!
- A file descriptor use for network communications is called a socket
- Just like with files:
- Your program can have multiple network channels open at once
- You need to pass a file descriptor to read () and write () to let the OS know which network channel to use In other words, we
specify the socket
to read/write on

## File Descriptor Table

OS's File Descriptor Table for the Process

| File <br> Descriptor | Type | Connection |  |
| :---: | :---: | :---: | :---: |
| 0 | pipe | stdin (console) |  |
| 1 | pipe | stdout (console) |  |
| 2 | pipe | stderr (console) |  |
| 3 | TCP <br> socket | local: 128.95.4.33:80 <br> remote: 44.1.19.32:7113 |  |
| 5 | file | index.html |  |
| 8 | file | pic.png |  |
| 9 | TCP <br> socket | local: $128.95 .4 .33: 80$ <br> remote: $102.12 .3 .4: 5544$ |  |
| $0,1,2$ always start as <br> stdin, stdout \& stderr. |  |  |  |

## Types of Sockets

## Stream sockets what we will focus on in 333

- For connection-oriented, point-to-point, reliable byte streams
- Using TCP, SCTP, or other stream transports
* Datagram sockets
- For connection-less, one-to-many, unreliable packets
- Using UDP or other packet transports
* Raw sockets
- For layer-3 communication (raw IP packet manipulation)

## Stream Sockets

* Typically used for client-server communications
- Client: An application that establishes a connection to a server
- Server: An application that receives connections from clients
- Can also be used for other forms of communication like peer-topeer

1) Establish connection:
client reaches out

2) Close connection:

```
- server
```

2) Communicate:

## Datagram Sockets

* Often used as a building block
- No flow control, ordering, or reliability, so used less frequently
- e.g. streaming media applications or DNS lookups

1) Create sockets:

- host
host

2) Communicate:

## The Sockets API

* Berkeley sockets originated in 4.2BSD Unix (1983)
- It is the standard API for network programming
- Available on most OSs
(- Written in C can still use these in C+t code You'll see some C-idioms and design practices.
* POSIX Socket API
- A slight update of the Berkeley sockets API
- A few functions were deprecated or replaced
- Better support for multi-threading was added

## Socket API: Client TCP Connection

* We'll start by looking at the API from the point of view of a client connecting to a server over TCP
* There are five steps:
[1) Figure out the IP address and port to which to connect **Today*
New
stuff 2) Create a socket

3) Connect the socket to the remote server
same as 54) read () and write () data using the socket
file I/0 5) Close the socket

Good Breakdown of this entire
process in section tomorrow

## Step 1: Figure Out IP Address and Port

* Several parts:
- Network addresses
- Data structures for address info C data structures : :
- DNS (Domain Name System) - finding IP addresses

## IPv4 Network Addresses

* An IPv4 address is a 4-byte tuple (232 addresses)
- For humans, written in "dotted-decimal notation"
- e.g. 128.95.4.1 (80:5f:04:01 in hex)
* IPv4 address exhaustion
- There are $2^{32} \approx 4.3$ billion IPv4 addresses
- There are $\approx 7.77$ billion people in the world (February 2020)

How many internet connected devices do each of us have?

## IPv6 Network Addresses

* An IPv6 address is a 16-byte tuple ( 2128 addresses ~about $3.4 \times 10^{38}$ )
- Typically written in "hextets" (groups of 4 hex digits)

2 rules for
human readability

- Can omit leading zeros in hextets

2. Double-colon replaces consecutive sections of zeros

- e.g. $2 \mathrm{~d} 01: \not 0 \mathrm{db} 8: \mathrm{f} 188: 0800: 0000: 0000: 0000: 1 \mathrm{f} 33$
- Shorthand: 2d01:db8:f188::1f33
- Transition is still ongoing
- IPv4-mapped IPv6 addresses
- 128.95.4.1 mapped to : : ffff:128.95.4.1 or : : ffff: 805f: 401
- This unfortunately makes network programming more of a headache ©

## Linux Socket Addresses

* Structures, constants, and helper functions available in
\#include <arpa/inet.h>
* Addresses stored in network byte order (big endian)
* Converting between host and network byte orders:
- uint32_t htonl(uint32_t hostlong);
- uint32_t ntohl (uint32_t netlong);
- ' h ' for host byte order and ' n ' for network byte order
- Also versions with ' $s$ ' for short (uint16_t instead)

First field in

* How to handle both IPv4 and IPv6?
- Use C structs for each, but make them somewhat similar
- Use defined constants to differentiate when to use each: AF _ INET for IPv4 and AF INET6 for IPv6(other types of sockets

## IPv4 Address Structures

struct sockaddr_in:

| family | port | addr | zero |
| :--- | :--- | :--- | :--- |
| 0 | 2 | 4 | 8 |

## Practice Question

* Assume we have a struct sockaddr_in that represents a socket connected to 198.35.26.96 (c6:23:1a:60) on port 80 ( $0 \times 50$ ) stored on a little-endian machine.
- AF_INET = 2
- Fill in the bytes in memory below (in hex):

## IPv6 Address Structures

struct sockaddr_in6:

| famport | flow |  |  |  |  |  |  |  |  |  |  |  |  |  |  | scope |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 24 |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 24 |  |

## Generic Address Structures

struct sockaddr*

```
// A mostly-protocol-independent address structure.
// Pointer to this is parameter type for socket system calls.
struct sockaddr { Family is always first to identify the socket type
    sa_family_t sa_family; // Address family (AF_* constants)
    char sa_data[14]; // Socket address (size varies
        // according to socket domain)
};
// A structure big enough to hold either IPv4 or IPv6 structs
struct sockaddr_storage { struct sockaddr
    sa_family_t ss_family; // Address family isn't bigenough for
    IP\veeG
    // padding and alignment; don't worry about the details
    char __ss_padl[_SS_PADISIZE];
    int64_t ___ss_align;
    char ___ss_pad2[_SS_PAD2SIZE];
};
```

- Commonly create struct sockaddr_storage, then pass pointer cast as struct sockaddr* to connect()

## Address Conversion

```
#include <stdlib.h>
    genaddr.cc
#include <arpa/inet.h>
int main(int argc, char **argv) {
    struct sockaddr_in sa; // IPv4
    struct sockaddr_in6 sa6; // IPv6
    // IPV4 string to sockaddr_in (192.0.2.1 = C0:00:02:01).
    inet_pton(AF_INET, "192.0.2.1", &(sa.sin_addr));
    // IPV6 string to sockaddr_in6.
    inet_pton(AF_INET6, "2001:d.b 8:63.b3:1::3490", &(sa6.sin6_addr));
    return EXIT_SUCCESS;
}
```

## Address Conversion

Addr src:
struct in_addr*
// or
struct in_6addr*

* const char* inet ntop(int af, const void* src, char* dst, socklen_t size);
- Converts network addr in src into buffer dst of size size
- Returns dst on success; NULL on error

```
#include <stdlib.h>
#include <arpa/inet.h>
int main(int argc, char **argv) {
    struct sockaddr_in6 sa6; // IPv6
    char astring[INET6_ADDRSTRLEN]; // IPv6
    // IPv6 string to sockaddr_in6.
    inet_pton(AF_INET6, "2001:0db8:63b3:1::3490", &(sa6.sin6_addr));
    // sockaddr_in6 to IPv6 string.
                                    If converting ipv4:
    inet_ntop(AF_INET6, &(sa6.sin6_addr), astring, INET6_ADDRSTRIEN);
    std::cout << astring << std::endl;|| 2001:0db8:63b3:1:3490
    return EXIT_SUCCESS;
}
```

## Domain Name System

* People tend to use DNS names, not IP addresses
- The Sockets API lets you convert between the two
- It's a complicated process, though:
- A given DNS name can have many IP addresses
- Many different IP addresses can map to the same DNS name
- An IP address will reverse map into at most one DNS name
- A DNS lookup may require interacting with many DNS servers
* You can use the Linux program "dig" to explore DNS
- dig @server name type (+short)
- server: specific name server to query
- type: A (IPv4), AAAA (IPv6), ANY (includes all types)

## DNS Hierarchy

## Resolving DNS Names

* The POSIX way is to use getaddrinfo ()
- A complicated system call found in \#include <netdb.h>
- int getaddrinfo(const char* hostname, const char* service, const struct addrinfo* hints, struct addrinfo** res)
- Tell getaddrinfo () which host and port you want resolved
- String representation for host: DNS name or IP address
- Set up a "hints" structure with constraints you want respected
- getaddrinfo () gives you a list of results packed into an "addrinfo" structure/linked list
- Returns 0 on success; returns negative number on failure
- Free the struct addrinfo later using freeaddrinfo ()

## getaddrinfo

* getaddrinfo() arguments:
- hostname - domain name or IP address string

Can use 0 or nullptr to indicate you don't want to filter results on that characteristic

- service - port \# (e.g. "80") or service name (e.g. "www") or NULI/nullptr
Hints Parameter

```
struct addrinfo {
    int ai_flags;
&int ai_family;
    int ai_socktype;
    int ai_protocol;
    size_t ai_addrlen;
&truct sockaddr* ai addr;
    char* ai_canonname;
&struct addrinfo* ai next;
// additional flags
// AF_INET, AF_INET6, AF_UNSPEC
// SOCK_STREAM, SOCK_DGRAM, 0
// IPPROTO_TCP, IPPROTO_UDP, O
// length of socket addr in bytes
pointer to socket addr
// canonical name
// can form a linked list
```

\};

## DNS Lookup Procedure

```
struct addrinfo {
    int ai_flags;
    int ai_family;
    int ai_socktype;
    int ai_protocol;
    size_t ai_addrlen;
    struct sockaddr* ai_addr;
    char* ai_canonname;
    struct addrinfo* ai_next;
};
```

1) Create a struct addrinfo hints
2) Zero out hints for "defaults"
3) Set specific fields of hints as desired
4) Call getaddrinfo() using \&hints
5) Resulting linked list res will have all fields appropriately set
