

CSE 333

Section 7

Client-side Networking

Netcat is listening on
port 80

Logistics

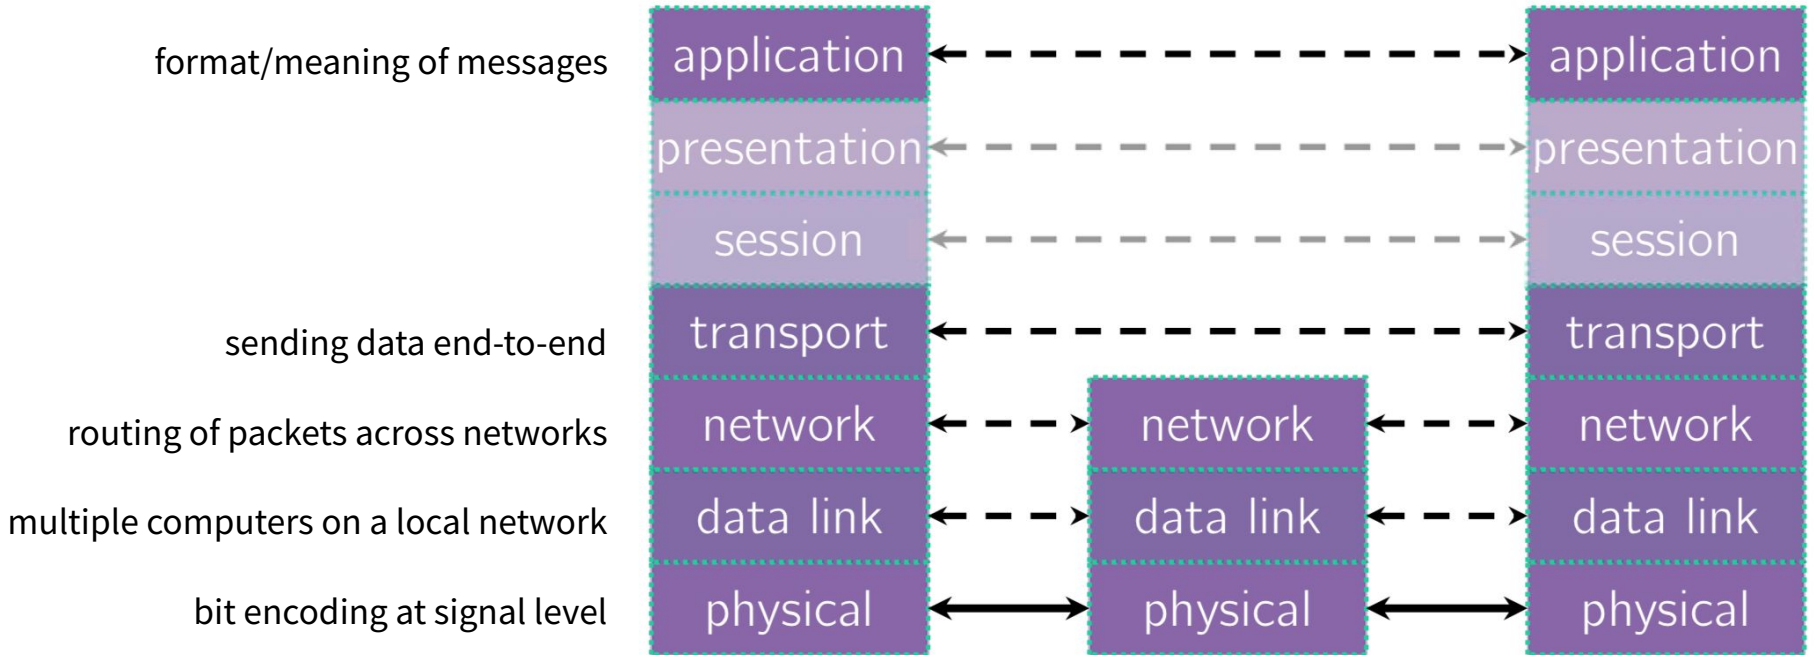

- Exercise 10:
 - Due **Wednesday** (8/10) @ 11:00am
- Exercise 11:
 - Due **Friday** (8/12) @ 11:00am
- Homework 3:
 - Due **Tonight** (8/04) @ 11:59pm
- Exploration Paper Proposal:
 - Due **Wednesday** (8/10) @ 11:59pm

Computer Networking Review

Computer Networks: A 7-ish Layer Cake

Computer Networks: A 7-ish Layer Cake

Data Flow

Exercise 1

Exercise 1

- DNS: Reliable transport protocol on top of IP.
 - IP: Translating between IP addresses and host names.
 - TCP: Sending websites and data over the Internet.
 - UDP: Unreliable transport protocol on top of IP.
 - HTTP: Routing packets across the Internet.
-

Computer Networks: A 7-ish Layer Cake

TCP versus UDP

Transmission Control Protocol (TCP):

- Connection-oriented Service
- Reliable and Ordered
- Flow control

User Datagram Protocol (UDP):

- “Connectionless” service
- Unreliable packet delivery
- High speed, no feedback

In what cases would we want to use TCP? UDP?

TCP guarantees reliability for things like messaging or data transfers. UDP allows for much higher speed for streaming applications (e.g., YouTube or Netflix).

The choice boils down to what your application prioritizes: reliability or speed.

Client-Side Networking

Client-Side Networking in 5 Easy* Steps!

1. Figure out what IP address and port to talk to
2. Build a socket from the client
3. Connect to the server using the client socket and server socket
4. Read and/or write using the socket
5. Close the socket connection

*difficulty is subjective

1. Figuring out the port and IP

- Performs a **DNS Lookup** for a hostname
- Use “hints” to specify constraints (struct addrinfo*)
- Get back a linked list of struct addrinfo results

```
int getaddrinfo(const char* hostname,  
               const char* service,  
               const struct addrinfo* hints,  
               struct addrinfo** res);
```

Name of host whose IP we want

We will set this to nullptr to get the default; otherwise you can specify service/port

Output parameter; *res is set to the first result in LL

Hints for the lookup server/refine results

What's A Socket? (Berkeley Sockets)

- Defines a local endpoint communication between server and client
 - Similar to a file descriptor for network communication
 - Built on various operating system calls
- Each socket is associated with **a port number (`uint16_t`)** and **an IP address**
 - Both port and address are stored in network byte order (big endian)
 - `ai_family` will help you to determine what is stored for your socket!

Obtaining your server's socket address

```
struct addrinfo {
    int ai_flags;           // additional flags
    int ai_family;         // AF_INET, AF_INET6, AF_UNSPEC
    int ai_socktype;       // SOCK_STREAM, SOCK_DGRAM, 0
    int ai_protocol;       // IPPROTO_TCP, IPPROTO_UDP, 0
    size_t ai_addrlen;     // length of socket addr in bytes
    struct sockaddr* ai_addr; // pointer to socket addr
    char* ai_canonname;     // canonical name
    struct addrinfo* ai_next; // can have linked list of records
}
```

- `ai_addr` points to a struct `sockaddr` describing a socket address, can be IPv4 or IPv6

Understanding struct sockaddr*

- It's just a pointer. To use it, we're going to have to dereference it and cast it to the right type (Very strange C "inheritance")
 - It is the endpoint your connection refers to

- Convert to a struct sockaddr_storage
 - Read the sa_family to determine whether it is IPv4 or IPv6
 - IPv4: AF_INET (macro) → cast to struct sockaddr_in
 - IPv6: AF_INET6 (macro) → cast to struct sockaddr_in6

Understanding Socket Addresses

struct sockaddr (pointer to this struct is used as parameter type in system calls)

fam	????
-----	------

....

struct sockaddr_in (IPv4)

fam	port	addr	zero
-----	------	------	------

16

struct sockaddr_in6 (IPv6)

fam	port	flow	addr	scope
-----	------	------	------	-------

28

struct sockaddr_storage

fam	
-----	--

Big enough to hold either

Building a Connection

2. Create a client socket to manage (returns an integer similar to a file descriptor in POSIX)

```
// returns file descriptor on success, -1 on failure (errno set)
int socket(int domain,           // AF_INET, AF_INET6, etc.
           int type,            // SOCK_STREAM, SOCK_DGRAM, etc.
           int protocol);      // just put 0 (network abstraction)
```

3. Use that created client socket to connect to the server socket

```
// Connects to the server
// returns 0 on success, -1 on failure (errno set)
int connect(int sockfd,          // socket file descriptor
            struct sockaddr *serv_addr, // socket addr of server
            socklen_t addrlen); // size of serv_addr
```

Usually from `getaddrinfo!`

Using your Connection (Steps 4 and 5)

```
// returns amount read, 0 for EOF, -1 on failure (errno set)
ssize_t read(int fd, void *buf, size_t count);
```

```
// returns amount written, -1 on failure (errno set)
ssize_t write(int fd, void *buf, size_t count);
```

```
// returns 0 for success, -1 on failure (errno set)
int close(int fd);
```

- Same POSIX methods we used for file I/O!
(so they require the same error checking...)

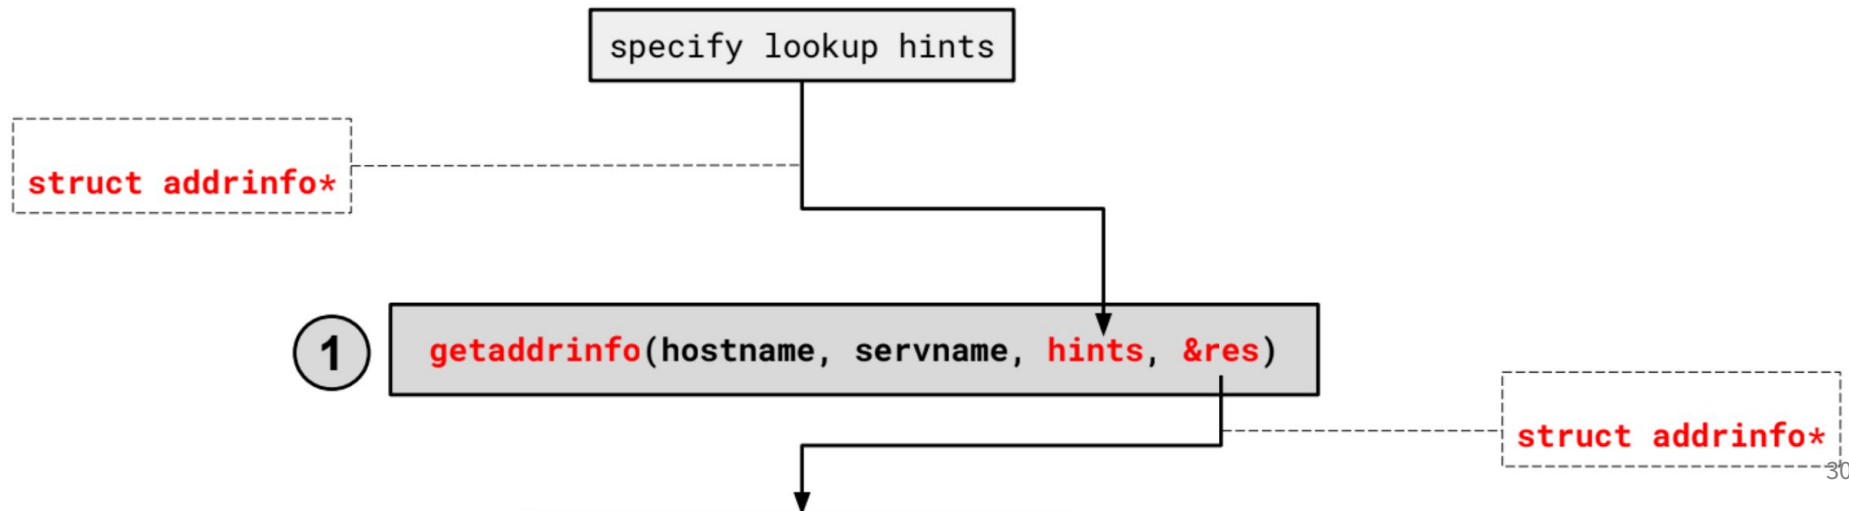

Exercise 2

1. getaddrinfo()

```
int getaddrinfo(const char* hostname,  
               const char* service,  
               const struct addrinfo* hints,  
               struct addrinfo** res);
```

- Performs a **DNS Lookup** for a hostname
- Use “hints” to specify constraints (struct addrinfo*)
- Get back a linked list of struct addrinfo results

1. getaddrinfo() - Interpreting Results

```
struct addrinfo {  
    int ai_family; // AF_INET, AF_INET6, AF_UNSPEC  
    struct sockaddr* ai_addr; // pointer to socket addr  
    ...  
};
```

- These records are dynamically allocated; you should pass the head of the linked list to `freeaddrinfo()`
- The field `ai_family` describes if it is IPv4 or IPv6
- `ai_addr` points to a `struct sockaddr` describing the socket address

1. getaddrinfo() - Interpreting Results

With a struct `sockaddr*`:

- The field `sa_family` describes if it is IPv4 or IPv6
- Cast to `struct sockaddr_in*` (v4) or `struct sockaddr_in6*` (v6) to access/modify specific fields
- Store results in a `struct sockaddr_storage` to have a space big enough for either

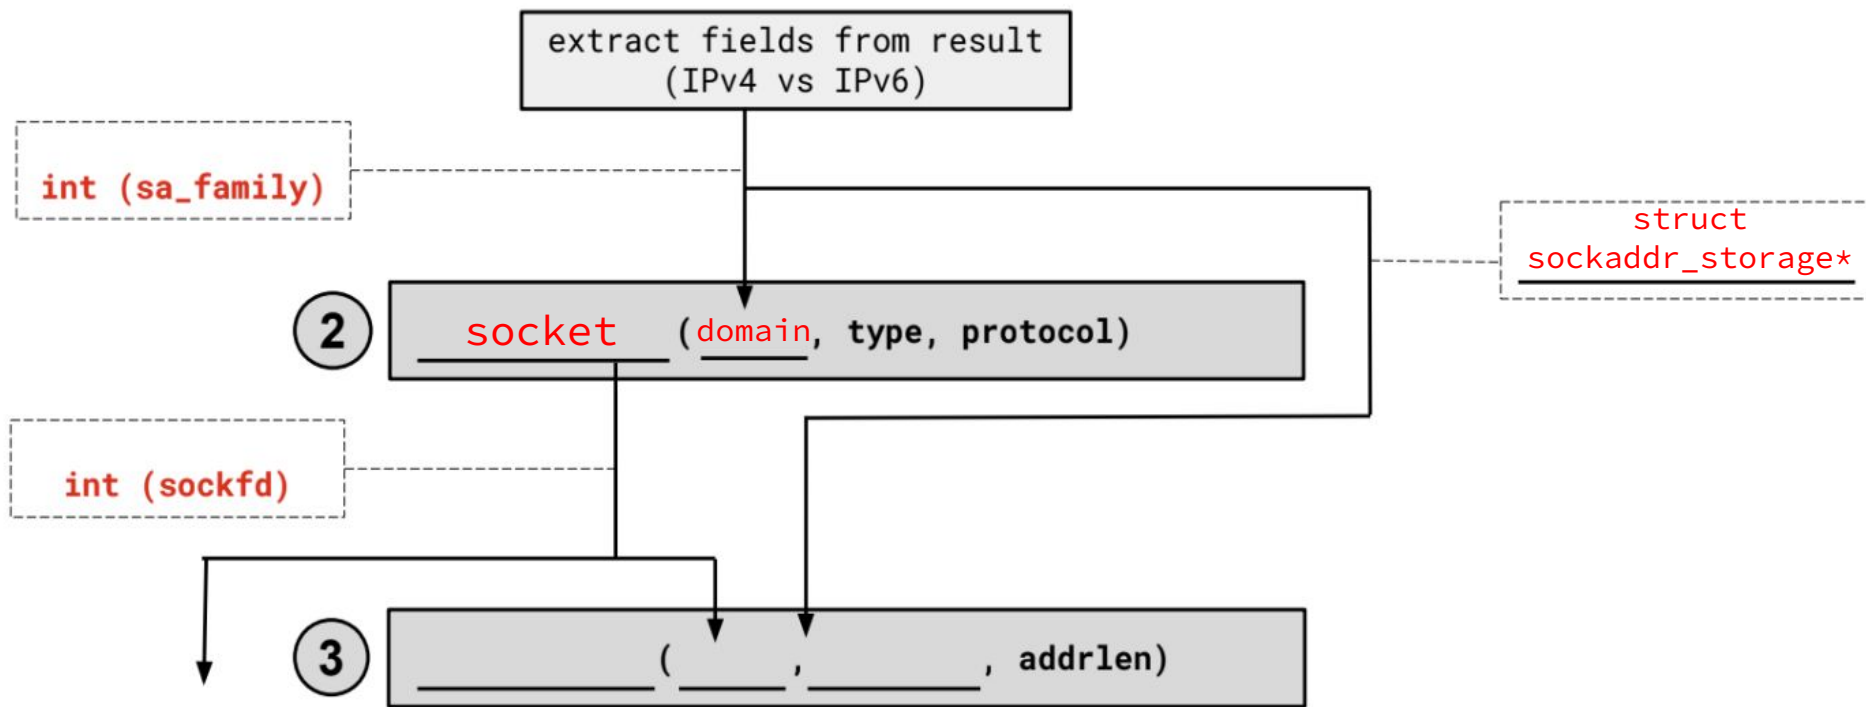

2. Build client side socket

```
int socket(int domain,      // AF_INET, AF_INET6
           int type,       // SOCK_STREAM (for TCP)
           int protocol);  // 0 for the default
```

- This gives us an unbound socket that's not connected to anywhere in particular
- Returns a socket file descriptor (we can use it everywhere we can use a normal file descriptor as well as in socket specific system calls)

2. Build client side socket

3. connect()

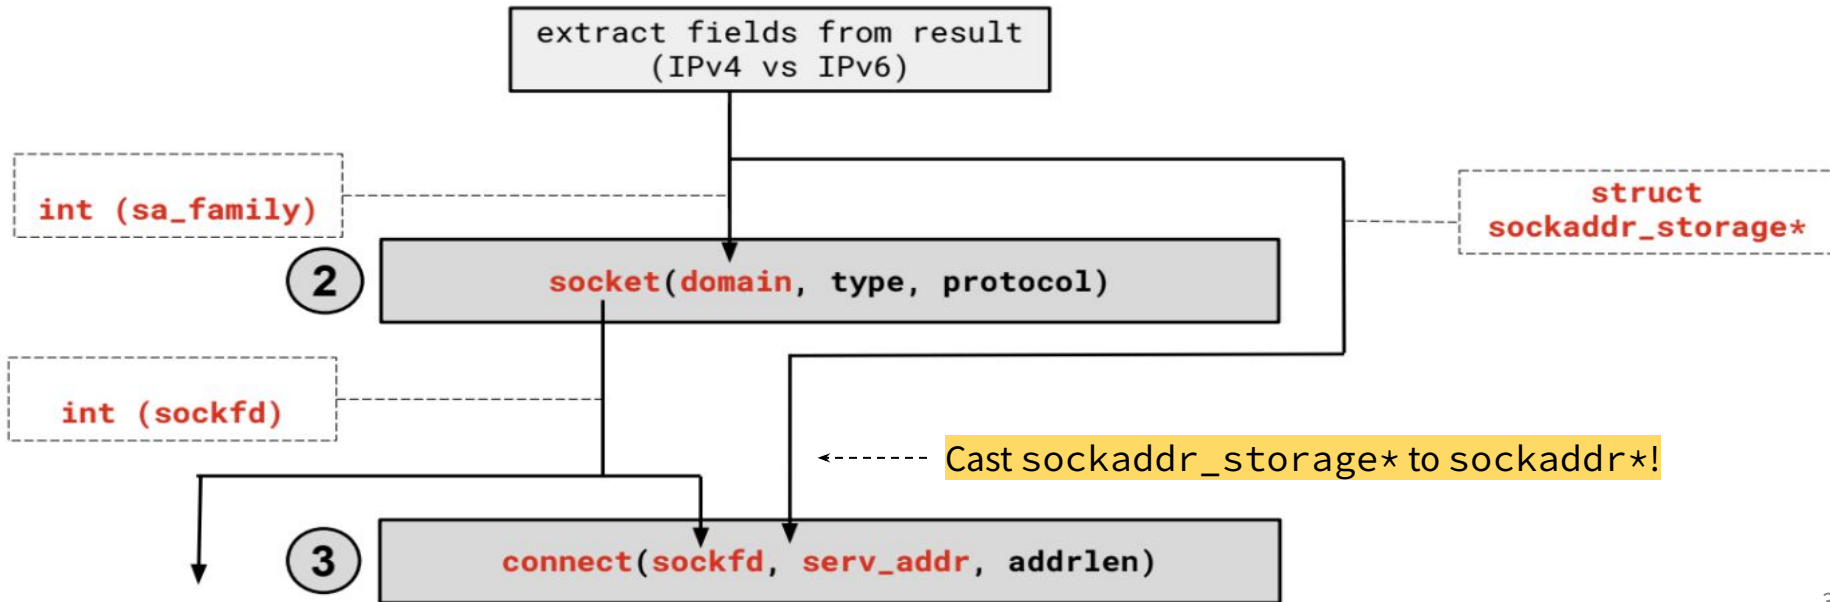

```
int connect(int socket,           // socket fd
            const struct sockaddr *addr, // address to connect to
            socklen_t addr_len);      // length of *addr
```

- This takes our unbound socket and connects it to the host at `addr`
- Returns 0 on success, -1 on error with `errno` set appropriately
- After this call completes, we can actually use our socket for communication!

3. connect()

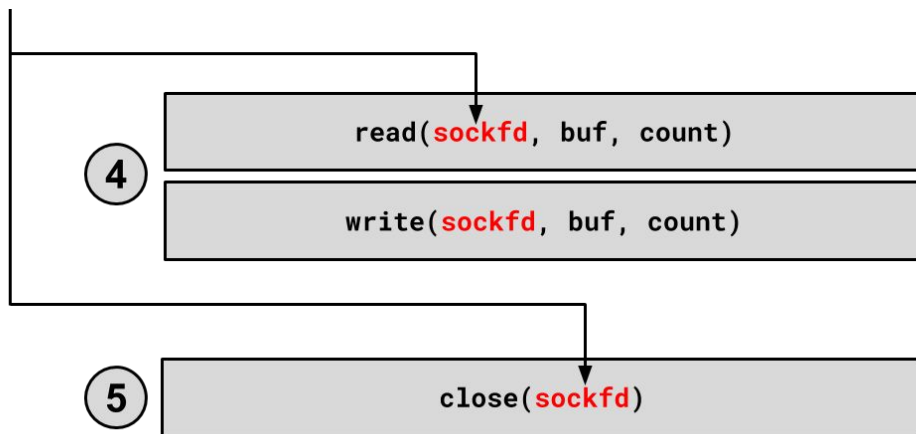

```
int connect(int socket, // from 1
            const struct sockaddr *addr, // from 2
            socklen_t addr_len); // size of serv_addr
```

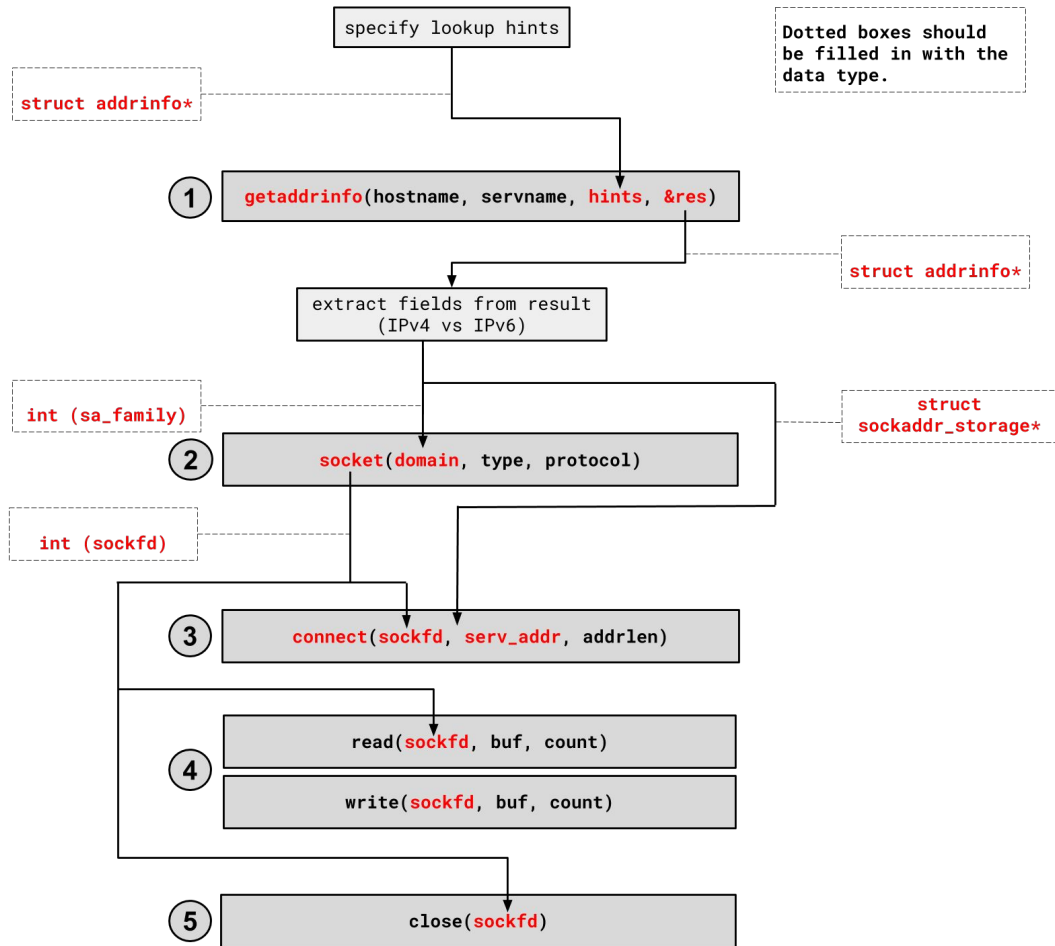

- Connects an available socket to a specified address
- Returns 0 on success, -1 on failure

4. read/write and 5. close

- Thanks to the file descriptor abstraction, use as normal!
- read from and write to a buffer, the OS will take care of sending/receiving data across the network
- Make sure to close the fd afterward

Using Netcat for the first time

netcat
