

# Final C Details

## CSE 333

**Instructor:** Hannah C. Tang

### Teaching Assistants:

Deeksha Vatwani	Hannah Jiang	Jen Xu
Leanna Nguyen	Nam Nguyen	Sayuj Shahi
Tanay Vakharia	Wei Wu	Yiqing Wang
Zohar Le		

# Lecture Outline

- ❖ Header Guards and Preprocessor Tricks
- ❖ Visibility of Symbols
  - `extern`, `static`

# Administrivia

- ❖ New exercise posted today, due Monday morning
- ❖ How far we get in lecture will dictate which exercise we post:
  - Ex4 = write a multi-file program
  - Ex5 = use today's best-practices and resubmit your program

# An #include Problem

- ❖ What happens when we compile `foo.c`?

```
struct pair {  
    int a, b;  
};
```

pair.h

```
#include "pair.h"  
  
// a useful function  
struct pair* make_pair(int a, int b);
```

util.h

```
#include "pair.h"  
#include "util.h"  
  
int main(int argc, char** argv) {  
    // do stuff here  
    ...  
    return EXIT_SUCCESS;  
}
```

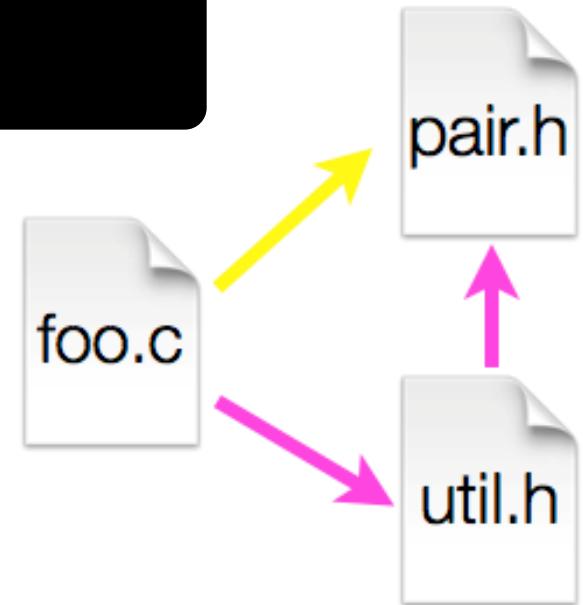

foo.c

# An #include Problem

- ❖ What happens when we compile `foo.c`?

```
bash$ gcc -Wall -g -o foo foo.c
In file included from util.h:1:0,
                 from foo.c:2:
pair.h:1:8: error: redefinition of 'struct pair'
  struct pair { int a, b; };
          ^
In file included from foo.c:1:0:
pair.h:1:8: note: originally defined here
  struct pair { int a, b; };
          ^
```

- ❖ `foo.c` includes `pair.h` twice!
  - Second time is indirectly via `util.h`
  - Struct definition shows up twice
    - Can see using `cpp`

# Header Guards

- ❖ A standard C Preprocessor trick to deal with this
  - Uses macro definition (`#define`) in combination with conditional compilation (`#ifndef` and `#endif`)

```
#ifndef PAIR_H_
#define PAIR_H_

struct pair {
    int a, b;
};

#endif // PAIR_H_
```

pair.h

```
#ifndef UTIL_H_
#define UTIL_H_

#include "pair.h"

// a useful function
struct pair* make_pair(int a, int b);

#endif // UTIL_H_
```

util.h

# Other Preprocessor Tricks

- ❖ A way to deal with “magic numbers” (constants)

```
int globalbuffer[1000];

void circalc(float rad,
             float* circumf,
             float* area) {
    *circumf = rad * 2.0 * 3.1415;
    *area = rad * 3.1415 * 3.1415;
}
```

Bad code  
(littered with magic constants)

```
#define BUFSIZE 1000
#define PI 3.14159265359

int globalbuffer[BUFSIZE];

void circalc(float rad,
             float* circumf,
             float* area) {
    *circumf = rad * 2.0 * PI;
    *area = rad * PI * PI;
}
```

Better code

# Macros

- ❖ You can pass arguments to macros

```
#define ODD(x) ((x) % 2 != 0)

void foo() {
    if ( ODD(5) )
        printf("5 is odd!\n");
}
```

cpp

```
void foo() {
    if ( ((5) % 2 != 0) )
        printf("5 is odd!\n");
}
```

- ❖ Beware of operator precedence issues!

- Use parentheses

```
#define ODD(x) ((x) % 2 != 0)
#define WEIRD(x) x % 2 != 0

ODD(5 + 1);

WEIRD(5 + 1);
```

cpp

```
((5 + 1) % 2 != 0);

5 + 1 % 2 != 0;
```

# Conditional Compilation

- ❖ You can change what gets compiled
  - In this example, `#define TRACE` before `#ifdef` to include debug `printf`s in compiled code

```
#ifdef TRACE
#define ENTER(f) printf("Entering %s\n", f);
#define EXIT(f)  printf("Exiting %s\n", f);
#else
#define ENTER(f)
#define EXIT(f)
#endif

// print n
void pr(int n) {
    ENTER("pr");
    printf("\n = %d\n", n);
    EXIT("pr");
}
```

ifdef.c

# Defining Symbols

- ❖ Besides `#defines` in the code, preprocessor values can be given as part of the `gcc` command:

```
bash$ gcc -Wall -g -DTRACE -o ifdef ifdef.c
```

- ❖ `assert` can be controlled the same way – defining `NDEBUG` causes `assert` to expand to “empty”
  - It’s a macro – see `assert.h`

```
bash$ gcc -Wall -g -DNDEBUG -o faster useassert.c
```

pollev.com/uwcse333

- ❖ What will happen when we try to compile and run?

```
bash$ gcc -Wall -DFOO -DBAR -o condcomp condcomp.c
bash$ ./condcomp
```

- A. Outputs "333"
- B. Outputs "334"
- C. Compiler message about EVEN
- D. Compiler message about BAZ
- E. We're lost...

```
#include <stdio.h>
#ifndef FOO
#define EVEN(x) ! (x%2)
#endif
#ifndef DBAR
#define BAZ 333
#endif

int main(int argc, char** argv) {
    int i = EVEN(42) + BAZ;
    printf("%d\n", i);
    return EXIT_SUCCESS;
}
```

# Lecture Outline

- ❖ Header Guards and Preprocessor Tricks
- ❖ **Visibility of Symbols**
  - `extern, static`

# Namespace Problem

- ❖ If we define a global variable named “counter” in one C file, is it visible in a different C file in the same program?
  - Yes, if you use external linkage
    - The name “counter” refers to the same variable in both files
    - The variable is *defined* in one file and *declared* in the other(s)
    - When the program is linked, the symbol resolves to one location
  - No, if you use internal linkage
    - The name “counter” refers to a different variable in each file
    - The variable must be *defined* in each file
    - When the program is linked, the symbols resolve to two locations

# External Linkage

- ❖ `extern` makes a *declaration* of something externally-visible

```
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// It has external linkage by
// default.
int counter = 1;

int main(int argc, char** argv) {
    printf("%d\n", counter);
    bar();
    printf("%d\n", counter);
    return EXIT_SUCCESS;
}
```

foo.c

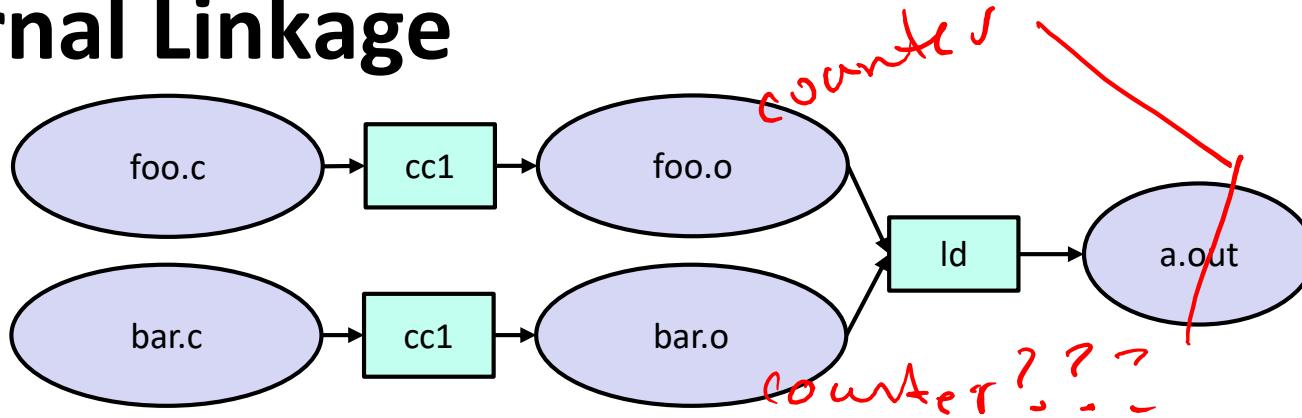

```
#include <stdio.h>

// "counter" is defined and
// initialized in foo.c.
// Here, we declare it, and
// specify external linkage
// by using the extern specifier.
extern int counter;

void bar() {
    counter++;
    printf("(b): counter = %d\n",
           counter);
}
```

bar.c

# External Linkage

```
#include <stdio.h>
```

```
// A global variable, defined and  
// initialized here in foo.c.  
// It has external linkage by  
// default.
```

```
int counter = 1;
```

```
int main(int argc, char* argv) {  
    printf("%d\n", counter);  
    bar();  
    printf("(a): counter = %d\n",  
        counter);  
    return EXIT_SUCCESS;  
}
```

foo.c

```
#include <stdio.h>
```

```
// "counter" is defined and  
// initialized in foo.c.  
// Here, we declare it, and  
// specify external linkage  
// by using the extern specifier.
```

```
extern int counter;
```

```
void bar() {  
    counter++;  
    printf("(b): counter = %d\n",  
        counter);  
}
```

bar.c

# Internal Linkage

- ❖ `static` (in the global context) restricts a definition to visibility within that file

```
#include <stdio.h>

// A global variable, defined and
// initialized here in foo.c.
// We force internal linkage by
// using the static specifier.
static int counter = 1;

int main(int argc, char** argv) {
    printf("%d\n", counter);
    bar();
    printf("%d\n", counter);
    return EXIT_SUCCESS;
}
```

foo.c

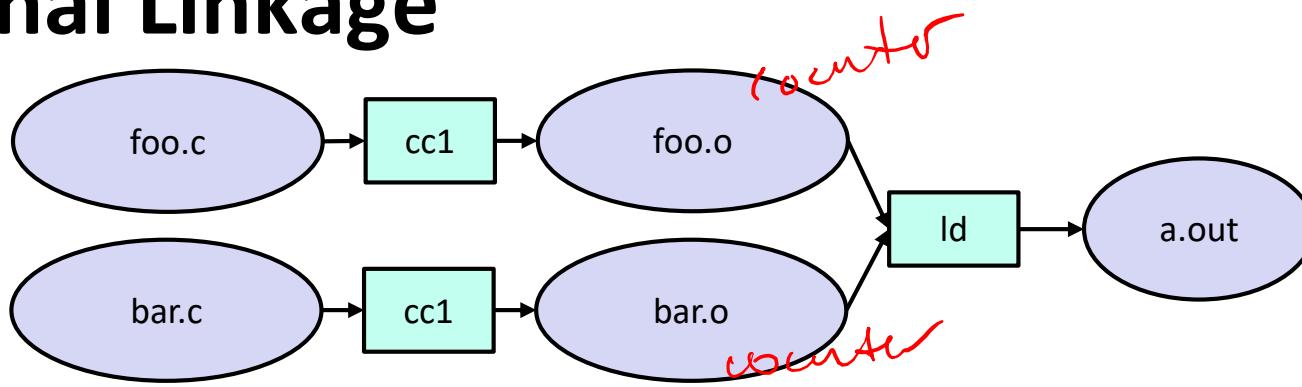

```
#include <stdio.h>

// A global variable, defined and
// initialized here in bar.c.
// We force internal linkage by
// using the static specifier.
static int counter = 100;

void bar() {
    counter++;
    printf("(b): counter = %d\n",
           counter);
}
```

bar.c

# Internal Linkage

```
#include <stdio.h>
```

```
// A global variable, defined and  
// initialized here in foo.c.  
// We force internal linkage by  
// using the static specifier.  
static int counter = 1;
```

```
int main(int argc, char* argv) {  
    printf("%d\n", counter);  
    bar();  
    printf("(b): %d\n", counter);  
    return EXIT_SUCCESS;  
}
```

foo.c

```
#include <stdio.h>
```

```
// A global variable, defined and  
// initialized here in bar.c.  
// We force internal linkage by  
// using the static specifier.  
static int counter = 100;
```

```
void bar() {  
    counter++;  
    printf("(b): counter = %d\n",  
           counter);  
}
```

bar.c

- ❖ Coming back to our NthPrime.h, NthPrime.c, and ex4.c, example, do either of these successfully link?

```
#define NUM_PRECALC 20
static int16_t
kPreCalculated[NUM_PRECALC] =
{2, 3, 5, 7, /* etc */};

int16_t NthPrime(int16_t n);
```

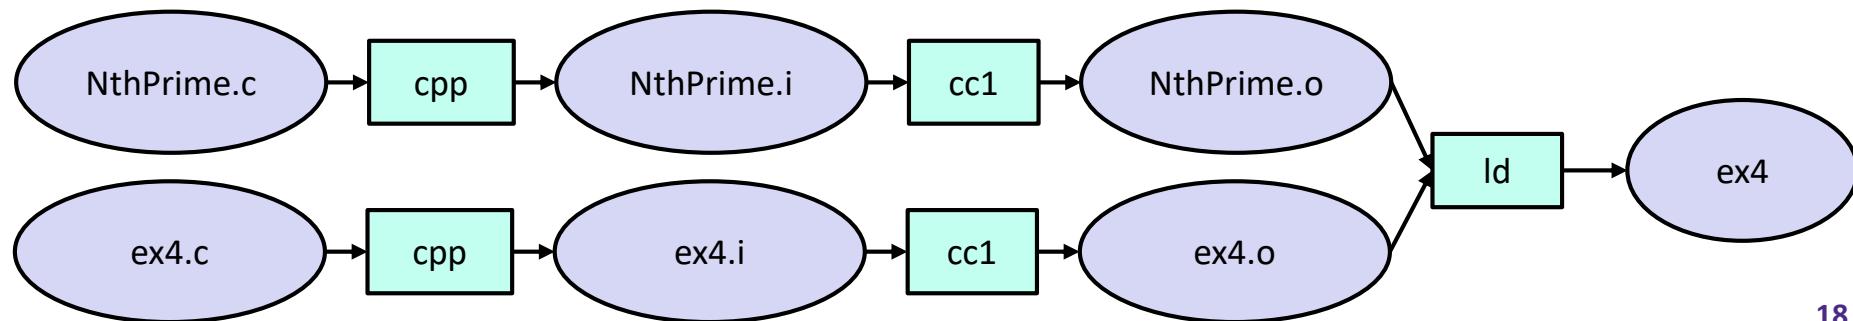

NthPrime.static.h

```
extern int16_t kPreCalculated[];

int16_t NthPrime(int16_t n);
```

NthPrime.extern.h

- ❖ (*you can assume NthPrime.c and ex4.c are unchanged*)

# Closing Thoughts

- ❖ Don't do either of these with an unchanged NthPrime.c!

```
#define NUM_PRECALC 20
static int16_t
kPreCalculated[NUM_PRECALC] =
{2, 3, 5, 7, /* etc */ };

int16_t NthPrime(int16_t n);
```

NthPrime.static.h

```
extern int16_t kPreCalculated[];

int16_t NthPrime(int16_t n);
```

NthPrime.extern.h

- ❖ Static variable in the header: every file that #includes the header will have its own private copy of the variable
  - Unnecessary data duplication!
- ❖ Extern variable in the header: the accompanying .c file must define the extern'ed variable for successful linkage

# Function Visibility

```
// By using the static specifier, we are indicating  
// that foo() should have internal linkage. Other  
// .c files cannot see or invoke foo().
```

```
static int foo(int x) {  
    return x*3 + 1;  
}
```

```
// Bar is "extern" by default. Thus, other .c files  
// could declare our bar() and invoke it.
```

```
int bar(int x) {  
    return 2*foo(x);  
}
```

bar.c

```
#include <stdio.h>
```

```
extern int bar(int x); // "extern" is default, usually omit.  
                      // should be in .h file, but effect is same
```

```
int main(int argc, char** argv) {  
    printf("%d\n", bar(5));  
    return EXIT_SUCCESS;  
}
```

main.c

# Linkage Issues

- ❖ Every global (variables and functions) is `extern` by default
  - Unless you add the `static` specifier, if some other module uses the same name, you'll end up with a collision!
    - Best case: compiler (or linker) error
    - Worst case: stomp all over each other
- ❖ It's good practice to:
  - Use `static` to “defend” your globals
    - Hide your private stuff!
  - Place external declarations in a module’s header file
    - Header is the public specification

# Static Confusion...

- ❖ C has a *different* use for the word “**static**”: to create a persistent *local* variable
  - The storage for that variable is allocated when the program loads, in either the `.data` or `.bss` segment
  - Retains its value across multiple function invocations
  - Confusing! Don’t use!! (But you may see it 😞)

```
void foo() {  
    static int count = 1; // static var, not auto!!  
    printf("foo has been called %d times\n", count++);  
}  
  
void bar() {  
    int count = 1;  
    printf("bar has been called %d times\n", count++);  
}  
  
int main(int argc, char** argv) {  
    foo(); foo(); bar(); bar(); return EXIT_SUCCESS;  
}
```

static\_extent.c

# Additional C Topics

- ❖ Teach yourself!
  - **man pages** are your friend!
  - String library functions in the C standard library
    - `#include <string.h>`
      - `strlen()`, `strcpy()`, `strdup()`, `strcat()`, `strcmp()`, `strchr()`, `strstr()`, ...
    - `#include <stdlib.h>` or `#include <stdio.h>`
      - `atoi()`, `atof()`, `sprint()`, `sscanf()`
  - How to declare, define, and use a function that accepts a variable-number of arguments (`varargs`)
  - unions and what they are good for
  - enums and what they are good for
  - Pre- and post-increment/decrement
  - Harder: the meaning of the “`volatile`” storage class

# Extra Exercise #1

- ❖ Write a program that:
  - Prompts the user to input a string (use `fgets()`)
    - Assume the string is a sequence of whitespace-separated integers  
(e.g. "5555 1234 4 5543")
  - Converts the string into an array of integers
  - Converts an array of integers into an array of strings
    - Where each element of the string array is the binary representation of the associated integer
  - Prints out the array of strings
