CSE 333 Section 9

Concurrency, pthreads

Logistics

- Homework 4
 - Due next Wednesday (5/29) @ 10:00pm
- Exercise 17
 - Due next Wednesday (5/29) @ 11:00am

pthreads

Concurrency with pthreads

EX17 and HW4 both use pthreads to create thread concurrency

Creation	pthread_create	Parent: "Go do this {function}"
Termination	pthread_ exit start_routine returns	Child: "I'm done with my task!"
	pthread_cancel	Parent: "I changed my mind, you can stop now"
Resource Clean-up	pthread_ join	Parent: "I'll wait for you to finish and report back your result" (resource persists until joined)
	pthread_detach	Parent: "You're free now, go forth and prosper" (automatically cleans up on termination)

pthread_create

- pthread_create creates a new thread into *thread, with attributes *attr
 (NULL means default attributes)
- Returns 0 on success and an error number on error (can check against error constants)
- The new thread runs start_routine(arg)
- Compile and link with -pthread.

Other Ways Threads Terminate

- Let the thread function exit by itself; work is done
- Thread calls pthread_exit (thread terminates its own execution)
- Main thread calls pthread_cancel to close a child thread.
- The process exits from main or calls exit

pthread_exit

```
void pthread_exit(void *retval);
```

- Equivalent of exit(retval); for a thread instead of a process
 - This means it is called in the thread function (child thread)
 - Will only terminate the thread instead of the entire process (other threads will still run)
- The thread will automatically exit once it returns from start_routine()
 - retval is an output parameter to indicate success or failure (usually pass the address of a global variable to view).

Synchronizing Threads – Called by Parent Thread

```
void pthread_join(pthread_t thread, void **retval);
```

- Waits for the thread specified by thread to terminate
- The thread equivalent of waitpid()
- The exit status of the terminated thread is placed in **retval

```
int pthread_detach(pthread_t thread);
```

 Mark thread specified by thread as detached – it will clean up its resources as soon as it terminates

```
int g = 0;
void *worker(void *ignore) {
 for (int k = 1; k \le 3; k++) {
   g = g + k;
 printf("g = %d\n", g);
  return NULL;
int main() {
  pthread_t t1, t2;
 int ignore;
  ignore = pthread_create(&t1, NULL, &worker, NULL);
  ignore = pthread create(&t2, NULL, &worker, NULL);
 pthread_join(t1, NULL);
  pthread_join(t2, NULL);
  return EXIT_SUCCESS;
```

What are the possible outputs of this program?

What is the range of values that g can have at the end of the program?

```
int g = 0;
void *worker(void *ignore) {
 for (int k = 1; k \le 3; k++) {
  g = g + k;
 printf("g = %d\n", g);
 return NULL;
int main() {
  pthread_t t1, t2;
 int ignore;
  ignore = pthread_create(&t1, NULL, &worker, NULL);
 ignore = pthread create(&t2, NULL, &worker, NULL);
 pthread_join(t1, NULL);
  pthread_join(t2, NULL);
  return EXIT_SUCCESS;
```

What are the possible outputs of this program?

Lots of possible answers, here are four:

```
g = 6 g = 12 g = 7 g = 6 g = 12 g = 12
```

```
int g = 0;
void *worker(void *ignore) {
 for (int k = 1; k \le 3; k++) {
   g = g + k;
 printf("g = %d\n", g);
  return NULL;
int main() {
  pthread_t t1, t2;
 int ignore;
  ignore = pthread_create(&t1, NULL, &worker, NULL);
 ignore = pthread_create(&t2, NULL, &worker, NULL);
 pthread_join(t1, NULL);
  pthread_join(t2, NULL);
  return EXIT_SUCCESS;
```

What is the range of values that g can have at the end of the program?

```
g = [4 - 12]
```

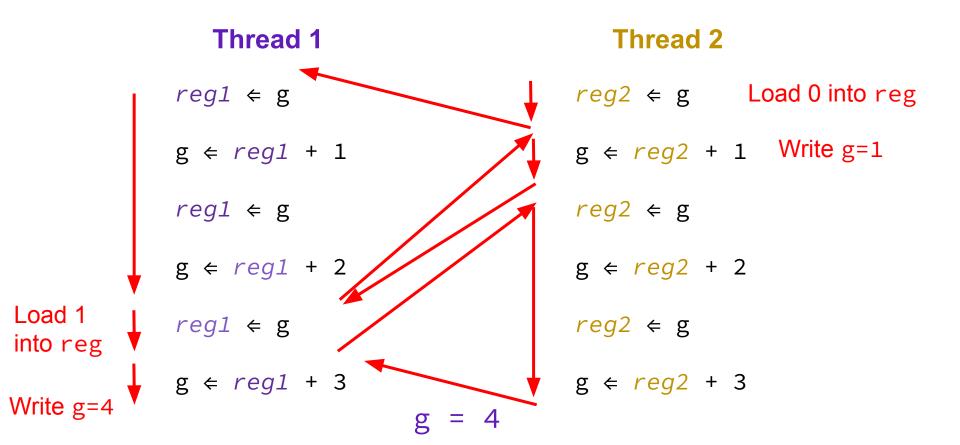

Assembly Instructions

Instructions for g = g + k:

mov	0x2ebf(%rip),%edx	Loads global g into local register
mov	-0x4(%rbp),%eax	Loads k into %eax register
add	%edx,%eax	Adds copy of g in %edx to %eax register
mov	<pre>%eax,0x2eb4(%rip)</pre>	Stores addition result back into global g

The "trick" is that because threads execute concurrently, the processor might be switched to a different thread after executing any instruction. When this sequence of code is executed, it could be interrupted between any two instructions by another thread that reads or writes global variable g.

Getting 4 from Exercise 1

Synchronization

Synchronization

- Remember, threads share an address space and system resources
- This makes it easy to communicate, but how do you avoid a total free-for-all?
- Protect your critical sections with locks!
 - Make sure nothing gets lost!
 - We'll be using pthread_mutex

No one: **Data Races:** Thread 2 Thread 3

Locking with mutex

- Initializes the mutex lock pointed to by mutex with lock attributes specified by attr.
- attr can be NULL.

```
int pthread_mutex_destroy(pthread_mutex_t *mutex);
```

- Destroys the lock
- Cleans up resource

Locking with mutex

```
int pthread_mutex_lock(pthread_mutex_t *mutex);
```

- Grabs the lock
- If resource is locked, function will be blocked until resource is unlocked

```
int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

Releases the lock

Problems with Synchronization

- Sharing Resources
 - Must be allocated / deallocated exactly once
 - Don't use deallocated resources from other threads

Problems with Synchronization

- Sharing Resources
 - Must be allocated / deallocated exactly once
 - Don't use deallocated resources from other threads
- Locking is hard!
 - Too much, and performance is worse than sequential
 - Too little, and threads clash often unexpected results (unwanted interleaving)
 - Not careful, and deadlock freezes your program forever

It's pay day! A CSE333 student wrote this program to pay all CSE TAs, answer the questions on the next slide (or on the worksheet) about this program.

```
// Assume all necessary libraries
                                      int main(int argc, char **argv) {
and header files are included
                                        pthread_t thds[NUM_TAS];
                                        pthread_mutex_init(&sum_lock, nullptr);
const int NUM TAS = 10;
static int bank accounts[NUM TAS];
                                        for (int i = 0; i < NUM TAS; i++) {
                                           int *num = new int(i);
static pthread_mutex_t sum_lock;
                                           if (pthread_create(&thds[i], nullptr, &thread_main, num)!= 0){
void *thread main(void *arg) {
                                             /*report error*/
  int *TA index =
     static_cast<int *>(arg);
  pthread mutex lock(&sum lock);
                                        for (int i = 0; i < NUM_TAS; i++) {</pre>
  bank accounts[*TA index] += 1000;
                                           cout << bank_accounts[i] << endl;</pre>
  pthread_mutex_unlock(&sum_lock);
  delete TA index;
  return nullptr:
                                        pthread_mutex_destroy(&sum_lock);
                                         return 0:
```

- a. Does the program increase the TAs' bank accounts correctly? Why or why not?
- b. Could we implement this program using processes instead of threads? Why would or why wouldn't we want to do this?
- c. Assume that all the problems, if any, are now fixed. The student discovers that the program they wrote is kinda slow even though its a multithreaded program. Why might it be the case? And how would you fix that?

a) Does the program increase the TAs' bank accounts correctly? Why or why not?

No, it's not correct. It requires main to call pthread_join to wait for each thread to finish before exiting the main program.

pthread_exit() will let a child thread finish leave to its parent, but it needs to be used in conjunction with pthread_join in order to check the results of the child thread.

b) Could we implement this program using processes instead of threads? Why would or why wouldn't we want to do this?

We could, but doing so would require some way for the processes to communicate with each other so that the data structure can be "shared" (remember that inter-process communication can be difficult and time consuming).

It is much easier to just use threads since each thread could directly access the data structure.

c) Assume that all the problems, if any, are now fixed. The student discovers that the program they wrote is kinda slow even though its a multithreaded program. Why might it be the case? And how would you fix that?

```
thread_mutex_lock(&sum_lock);
bank_accounts[*TA_index] += 1000;
pthread_mutex_unlock(&sum_lock);

thread_mutex_lock(&acct_lcks[*TA_index]);
bank_accounts[*TA_index] += 1000;
pthread_mutex_unlock(&acct_lks[*TA_index]);
```

Only one thread can increase the value of one account at a time and there is no difference from incrementing each account sequentially because we only have a single lock on this line for every single thread to share.

To fix this, we can have one lock per account so that multiple threads can increment the account at the same time. (An alternative solution is to just not use locks as well since the threads made will not conflict with each other, but we should aim for safe options for the bank accounts)
