Concurrency: Processes CSE 333 Winter 2024

Instructor: Hal Perkins

Teaching Assistants:

Ann Baturytski Noa Ferman Hannah Jiang

Humza Lala Leanna Nguyen Varun Pradeep

Justin Tysdal Deeksha Vatwani Yiqing Wang

Wei Wu Jennifer Xu

Administrivia

- hw4 due Thursday night
 - Usual late days (2 max) apply if you have any remaining
- Final exam Tue. March 12, 12:30-2:20, Gowen 201 & 301
 - Review session Mon., March 11, 4:30-~5:30, ECE 105
 - Topic list on the web now; exam will be somewhat weighted towards 2nd half of the quarter
 - Closed book but you may have two 5x8 cards with handwritten notes
 - Free blank cards available after class
- Please nominate great TAs for the Bandes award when nominations are available
- Please fill out course evals while they are available

Outline

- * searchserver
 - Sequential
 - Concurrent via forking threads pthread_create()
 - Concurrent via forking processes fork ()
 - Concurrent via non-blocking, event-driven I/O select()
 - We won't get to this 🕾

 Reference: Computer Systems: A Programmer's Perspective, Chapter 12 (CSE 351 book)

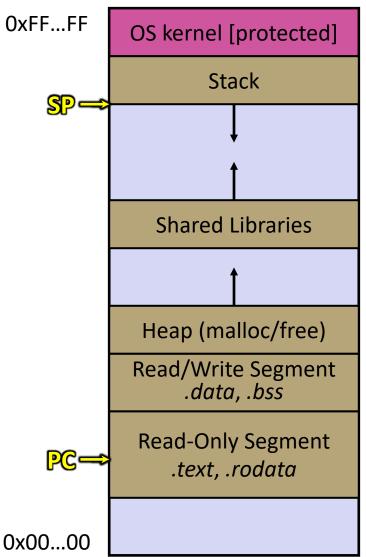

Creating New Processes

pid_t fork(void);

- Creates a new process (the "child") that is an exact clone* of the current process (the "parent")
 - *Everything is cloned except threads: variables, file descriptors, open sockets, the virtual address space (code, globals, heap, stack), etc.
- Primarily used in two patterns:
 - Servers: fork a child to handle a connection
 - Shells: fork a child that then exec's a new program

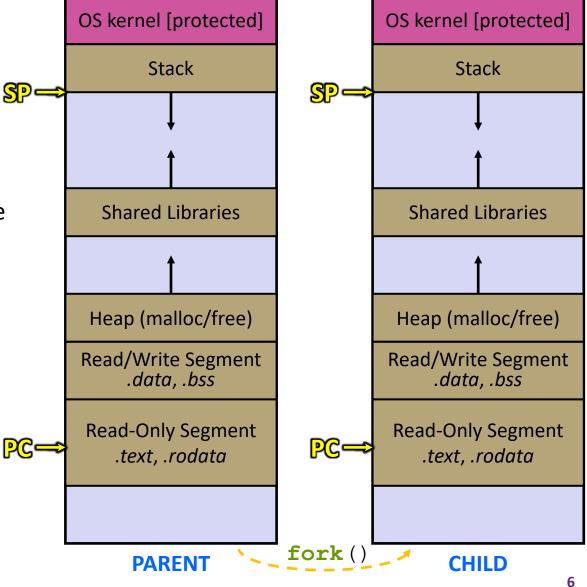

fork() and Address Spaces

- A process executes within an address space
 - Includes segments for different parts of memory
 - Process tracks its current state using the stack pointer (SP) and program counter (PC)

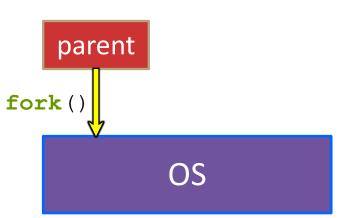

fork() and Address Spaces

- Fork cause the OS to clone the address space
 - The *copies* of the memory segments are (nearly) identical
 - The new process has copies of the parent's data, stack-allocated variables, open file descriptors, etc.

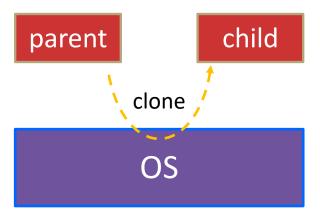

fork()

- fork() has peculiar semantics
 - The parent invokes fork ()
 - The OS clones the parent
 - Both the parent and the child return from fork
 - · Parent receives child's pid
 - Child receives a 0

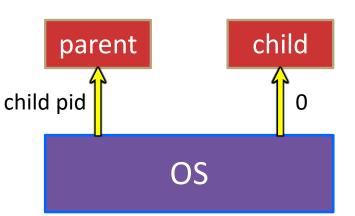

fork()

- fork() has peculiar semantics
 - The parent invokes fork ()
 - The OS clones the parent
 - Both the parent and the child return from fork
 - · Parent receives child's pid
 - Child receives a 0

fork()

- fork() has peculiar semantics
 - The parent invokes fork ()
 - The OS clones the parent
 - Both the parent and the child return from fork
 - Parent receives child's pid
 - Child receives a 0

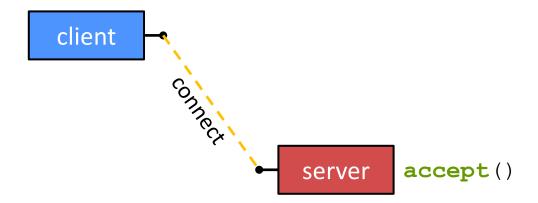

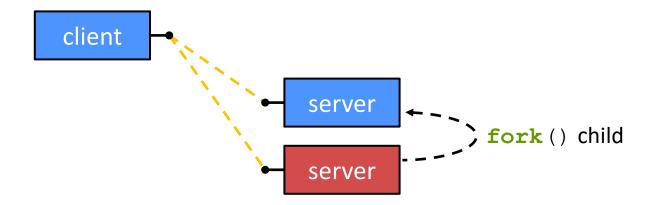

* See fork_example.cc

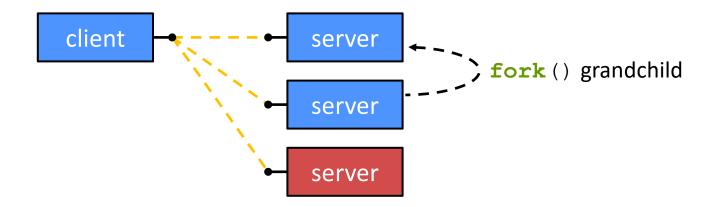

Concurrent Server with Processes

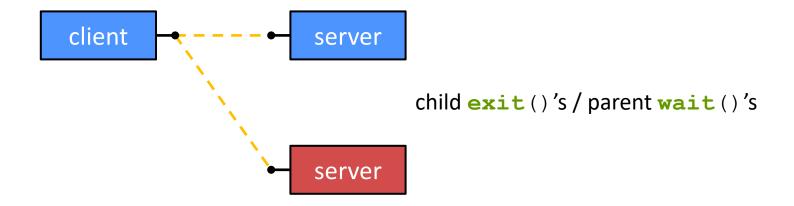

- The parent process blocks on accept(), waiting for a new client to connect
 - When a new connection arrives, the parent calls fork() to create a child process
 - The child process handles that new connection and exit()'s when the connection terminates
- Remember that children become "zombies" after termination
 - Option A: Parent calls wait() to "reap" children
 - Option B: Use a double-fork trick

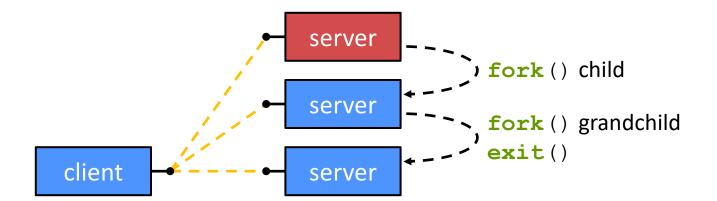

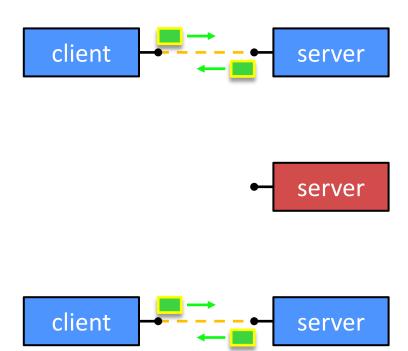

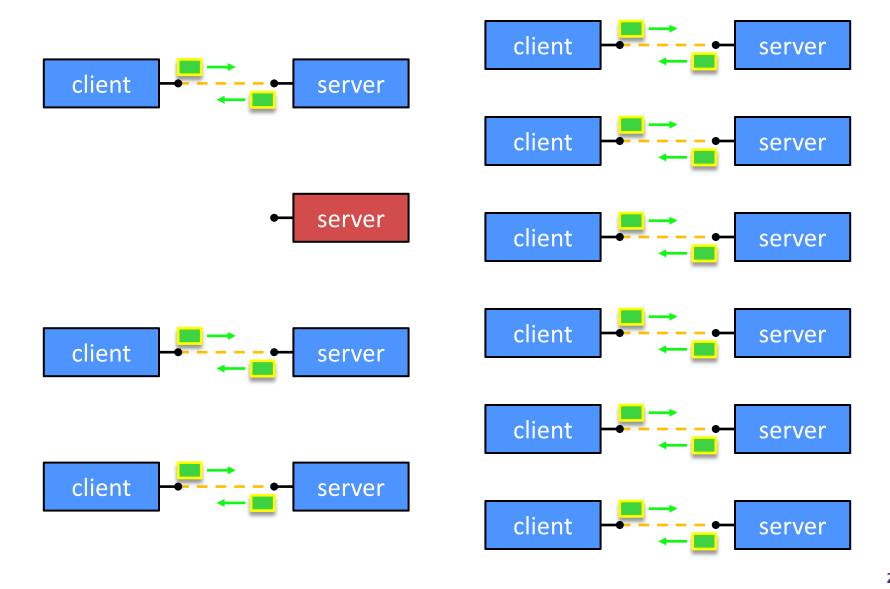

Concurrent with Processes

See searchserver_processes/

Whither Concurrent Processes?

Advantages:

- Almost as simple to code as sequential
 - In fact, most of the code is identical!
- Concurrent execution leads to better CPU, network utilization

Disadvantages:

- Processes are heavyweight
 - Relatively slow to fork
 - Context switching latency is high
- Communication between processes is complicated

How Fast is fork()?

* See forklatency.cc

- ~ 0.25 ms per fork*
 - \therefore maximum of (1000/0.25) = 4,000 connections/sec/core
 - ~350 million connections/day/core
 - This is fine for most servers
 - Too slow for super-high-traffic front-line web services
 - Facebook served ~ 750 billion page views per day in 2013!
 Would need 3-6k cores just to handle fork(), i.e. without doing any work for each connection
- *Past measurements are not indicative of future performance depends on hardware, OS, software versions, ...

How Fast is pthread_create()?

* See threadlatency.cc

- - ~10x faster than fork ()
 - \therefore maximum of (1000/0.036) = 28,000 connections/sec
 - ~2.4 billion connections/day/core
- Much faster, but writing safe multithreaded code can be serious voodoo
- *Past measurements are not indicative of future performance depends on hardware, OS, software versions, ..., but will typically be an order of magnitude faster than fork()

Aside: Thread Pools

- In real servers, we'd like to avoid overhead needed to create a new thread or process for every request
- Idea: Thread Pools:
 - Create a fixed set of worker threads or processes on server startup and put them in a queue
 - When a request arrives, remove the first worker thread from the queue and assign it to handle the request
 - When a worker is done, it places itself back on the queue and then sleeps until dequeued and handed a new request

More Administrivia

- We're done with concurrency
- So what should we do about class on Wednesday?
- Proposal: no class Wednesday
 - Use the extra time to wrap up hw4
- See you on Friday to wrap up the quarter
 - But be sure to go to sections on Thursday!!
