Relevant Course Information

- Exercise 7 not due until next Wed (11/4); focus on HW2 and Midterm
- Homework 2 due tomorrow (10/29)
  - Don't forget to clone your repo to double-check compilation!
  - Feel free to use late days if you can't finish & polish your submission – they exist for a reason
  - Don't modify header files, we will test with the original `.h` files
- Midterm: Monday, November 2 (see Ed post #300)
  - GUG 220 or ARC 147, depending on your *registered* quiz section
  - Reference sheet and two-sided *handwritten* cheat sheet!
  - Midterm review session on Friday (2/6) from 4:30–6:20 PM (See Ed post #304)
  - Practice midterms and solutions on the course website

Lecture Outline

- Templates

Suppose that…

- You want to write a function to compare two `int`s
- You want to write a function to compare two `string`s
  - Function overloading!

```
// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
int compare(const int& value1, const int& value2) {
  if (value1 < value2) return -1;
  if (value2 < value1) return  1;
  return 0;
}

// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
int compare(const string& value1, const string& value2) {
  if (value1 < value2) return -1;
  if (value2 < value1) return  1;
  return 0;
}
```

does something different in each case

Hm…

- The two implementations of `compare` are nearly identical!
  - What if we wanted a version of `compare` for *every* comparable type?
  - We could write (many) more functions, but that's obviously wasteful and redundant too much repeated code!

- What we'd prefer to do is write "*generic code*"
  - Code that is type-independent (*i.e.*, polymorphic across types)

C++ Parametric Polymorphism

- C++ has the notion of templates
  - A function or class that accepts a ***type*** as a parameter
    - You define the function or class once in a type-agnostic way
    - When you invoke the function or instantiate the class, you specify (one or more) types or values as arguments to it
    - This is in addition to the normal function parameters
  - At ***compile-time***, the compiler will generate the "specialized" code from your template using the types you provided
    - Your template definition is NOT runnable code
    - Code is *only* generated if you use your template

Function Templates

- Template to **`compare`** two "things":

```
#include <iostream>
#include <string>

// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
template <typename T>   // <...> can also be written <class T>
int compare(const T& value1, const T& value2) {
  if (value1 < value2) return -1;
  if (value2 < value1) return  1;
  return 0;
}

int main(int argc, char* argv[]) {
  std::string h("hello"), w("world");
  std::cout << compare<int>(10, 20) << std::endl;          // -1
  std::cout << compare<std::string>(h, w) << std::endl;    // -1
  std::cout << compare<double>(50.5, 50.6) << std::endl;   // -1
  return EXIT_SUCCESS;
}
```

template parameter list (also written as: <class T>)

template function definition

T only needs to implement < to work with compare()

explicit template arguments (3 different instances of compare)

functiontemplate.cc

Compiler Inference

- Same thing, but letting the compiler infer the types:

functiontemplate_infer.cc

```
#include <iostream>
#include <string>

// returns 0 if equal, 1 if value1 is bigger, -1 otherwise
template <typename T>
int compare(const T& value1, const T& value2) {
  if (value1 < value2) return -1;
  if (value2 < value1) return  1;
  return 0;
}

int main(int argc, char* argv[]) {
  std::string h("hello"), w("world");
  std::cout << compare(10, 20) << std::endl; // ok
  std::cout << compare(h, w) << std::endl;   // ok
  std::cout << compare("Hello", "World") << std::endl;  // hm...
  return EXIT_SUCCESS;
}
```

infer int, -1

infer std::string, -1

infer char*, could be ±1 (based on addresses)

no explicit template argument

Template Non-types

- You can use non-types (constant values) in a template:

valtemplate.cc

```
#include <iostream>
#include <string>

// return pointer to new N-element heap array filled with val
// (not entirely realistic, but shows what's possible)
template <typename T, int N>
T* valarray(const T& val) {
  T* a = new T[N];
  for (int i = 0; i < N; ++i)
    a[i] = val;
  return a;
}

int main(int argc, char* argv[]) {
  int* ip = valarray<int, 10>(17);
  string* sp = valarray<string, 17>("hello");
  ...
}
```

separate template arguments with commas like normal

What's Going On?

- The compiler doesn't generate any code when it sees the template function definition
  - It doesn't know what code to generate yet, since it doesn't know what types are involved – different behavior for different types!
- Only When the compiler sees the function being used, then it understands what types are involved
  - It generates the ***instantiation*** of the template and compiles it (kind of like macro expansion)
    - The compiler generates template instantiations for *each* type used as a template parameter

The Great Tragedy of C++ Templates

```
#ifndef COMPARE_H_
#define COMPARE_H_

template <typename T>
int comp(const T& a, const T& b);

#endif  // COMPARE_H_
```

compare.h

```
#include <cstdlib>
#include <iostream>

#include "compare.h"

using std::cout;
using std::endl;

int main(int argc, char* argv[]) {
  cout << comp<int>(10, 20);
  cout << endl;
  return EXIT_SUCCESS;
}
```

main.cc

g++ -c compare.cc → empty compare.o!

```
#include "compare.h"  (no usage of comp< >)

template <typename T>
int comp(const T& a, const T& b) {
  if (a < b) return -1;
  if (b < a) return 1;
  return 0;
}
```

compare.cc

g++ -c main.cc → main.o without definition of comp<int>

g++ main.o compare.o → linker error (no comp<int>)

Solution #1 (Google Style Guide prefers)

STYLE TIP

```
#ifndef COMPARE_H_
#define COMPARE_H_

template <typename T>
int comp(const T& a, const T& b) {
  if (a < b) return -1;
  if (b < a) return 1;
  return 0;
}

#endif  // COMPARE_H_
```

compare.h

```
#include <cstdlib>
#include <iostream>

#include "compare.h"

using std::cout;
using std::endl;

int main(int argc, char* argv[]) {
  cout << comp<int>(10, 20);
  cout << endl;
  return EXIT_SUCCESS;
}
```

main.cc

less implementation hiding! :(

Solution #2 (you'll see this sometimes)

```
#ifndef COMPARE_H_
#define COMPARE_H_

template <typename T>
int comp(const T& a, const T& b);

#include "compare.cc"

#endif  // COMPARE_H_
```

compare.h

```
template <typename T>
int comp(const T& a, const T& b) {
  if (a < b) return -1;
  if (b < a) return 1;
  return 0;
}
```

compare.cc

```
#include <cstdlib>
#include <iostream>

#include "compare.h"

using std::cout;
using std::endl;

int main(int argc, char* argv[]) {
  cout << comp<int>(10, 20);
  cout << endl;
  return EXIT_SUCCESS;
}
```

main.cc

Poll Everywhere

pollev.com/cse333

Which is the *simplest* way to compile our program (`a.out`)?

- Assume we are using Solution #2 (`.h` includes `.cc`)

A. `g++ main.cc`

B. `g++ main.cc compare.cc`

C. `g++ main.cc compare.h`

D. `g++ -c main.cc`
`g++ -c compare.cc` → empty compare.o
`g++ main.o compare.o`

E. We're lost…

template definition added to main.cc via #include by preprocessor (main.cc → compare.h → compare.cc)

all of these command sets will work, but crossed out parts are unnecessary.

Make file

```
a.out: main.cc compare.h compare.cc
    g++ main.cc
```

Class Templates

- Templates are useful for classes as well
  - (In fact, that was one of the main motivations for templates!)

- Imagine we want a class that holds a pair of things. Users of the class can:
  - Set the value of the first thing
  - Set the value of the second thing
  - Get the value of the first thing
  - Get the value of the second thing
  - Swap the values of the things
  - Print the pair of things

Pair Class Definition

Pair.h

```
#ifndef PAIR_H_
#define PAIR_H_

template <typename Thing>
class Pair {
 public:          //default constructor
  Pair() { };

  Thing get_first() const { return first_; }
  Thing get_second() const { return second_; }
  void  set_first(const Thing& copyme);
  void  set_second(const Thing& copyme);
  void  Swap();

 private:
  Thing first_, second_;
};

#include "Pair.cc"

#endif  // PAIR_H_
```

template class definition

inline definitions

declarations

could be primitive or another class

← following Solution #2 (for ease of slide separation)

Pair Function Definitions

Pair.cc

```
template <typename Thing>
void Pair<Thing>::set_first(const Thing& copyme) {
  first_ = copyme;
}

template <typename Thing>
void Pair<Thing>::set_second(const Thing& copyme) {
  second_ = copyme;
}

template <typename Thing>
void Pair<Thing>::Swap() {
  Thing tmp = first_;
  first_ = second_;
  second_ = tmp;
}
// nonmember template function to print out Pair values
template <typename T>
std::ostream& operator<<(std::ostream& out, const Pair<T>& p) {
  return out << "Pair(" << p.get_first() << ", "
             << p.get_second() << ")";
}
```

template function for template class member function

member of template class instantiation with Thing

Using Pair

```
#include <iostream>
#include <string>

#include "Pair.h"

int main(int argc, char* argv[]) {
  Pair<std::string> ps;  // invokes default constructor
  std::string x("foo"), y("bar");

  ps.set_first(x);   //  ("foo", "")
  ps.set_second(y);  //  ("foo", "bar")
  ps.Swap();         //  ("bar", "foo")
  std::cout << ps << std::endl;  // invoke nonmember operator<< function

  return EXIT_SUCCESS;
}
```

usepair.cc

Class Template Notes (look in *Primer* for more)

- `Thing` is replaced with template argument when class is instantiated
- Class template parameters are in scope everywhere within the class's curly braces { }
  - Inline methods in the class's {}s don't need a `template<>` line above them.
  - Method definitions outside of the {}s must have a `template<>` line above them, with the same parameters
    - The names *should* match, but don't need to
- Only template methods that actually get called in your program are instantiated (but this is an implementation detail)

Review Questions (Classes and Templates)

- Why are only `get_first()` and `get_second()` const?

  the accessors don't modify the class instance — the mutators and swap do
  — operator << is a non-member function

- Why do the accessor methods return `Thing` and not references?

  returning a reference to a private member violates the 'private' modifier, so we instead return a copy of Thing

- Why is `operator<<` not a `friend` function?

  it doesn't need access to private data members because it uses the accessors instead

- What happens in the default constructor when `Thing` is a class?

  data members still get initialized — in this case, invoke the default constructor of Thing for first_ and second_

- In the execution of `Swap()`, how many times are each of the following invoked (assuming `Thing` is a class)?

  ctor 0 cctor 1 (tmp) op= 2 (first_, second_) dtor 1 (tmp)
