

Systems Programming

The Rust Programming Language

Instructors:

Amber Hu

Justin Hsia

Teaching Assistants:

Ally Tribble

Blake Diaz

Connor Olson

Grace Zhou

Jackson Kent

Janani Raghavan

Jen Xu

Jessie Sun

Jonathan Nister

Mendel Carroll

Rose Maresh

Violet Monserate

Relevant Course Information

- ❖ We are finished with testable course content! 🍦
 - Today's content and Friday's wrap-up lecture will not be tested
- ❖ HW 4 is due tomorrow @ 11:59 PM
- ❖ Course evals
 - Separate lecture and section evals
 - Lecture has only 17 responses out of 203 so far!
- ❖ Final Exam is Wednesday, 3/11 @ 12:30-2:20 PM
 - Kane Hall 110 and 120
 - See [Ed post #630](#)
 - Final review session on Friday @ 4:30-6:20 PM, CSE2 G10 + Zoom

Lecture Overview

- ❖ **Why is C/C++ difficult?**
- ❖ Rust programming language
- ❖ C/C++ vs. Rust
 - Type safety
 - Defaults
 - Memory safety
 - Race conditions
 - Tools

Why is Writing (Good) C/C++ Difficult?

- ❖ Tools
 - Compilation/linking is hard, Makefiles are tedious
 - Error messages are inscrutable, esp. linking and template errors
- ❖ Weird defaults
 - Functions in global namespace, mutable by default, `char` = 1 byte
- ❖ Type (un)safety
 - Reinterpreting bits, `void*`
- ❖ Memory errors
 - No bounds checking, invalid pointer dereferencing
- ❖ Data races
 - Hard to keep track of which memory is shared b/w threads
 - Not exclusive to C/C++

Why Write New C/C++?

- ❖ Despite all this, new C/C++ code remains common
 - Why?
- ❖ Backwards compatibility
 - Legacy C code is everywhere
 - C++ allows us to directly build on top of legacy systems
- ❖ Close to the hardware
 - Embedded systems (IoT, robotics, vehicles) often require granular control of hardware only exposed in C
 - High performance applications are often written in C with a high-level wrapper (*e.g.*, `numpy` in Python)

Enter: The Rust Programming Language

- ❖ Rust is a language designed to both:
 - Fill the **niche** that C/C++ currently occupy, and...
 - **Fix** what makes writing good C/C++ difficult

- ❖ Overview
 - No runtime or garbage collection
 - Compiles to a variety of assembly/OS targets
 - Type system provides **strong** compile-time guarantees
 - Safe Rust eliminates all data races, memory leaks, and invalid reads
 - “Fearless concurrency” — [The Rust Book](#)
 - Tooling designed for productivity
 - Built-in package manager and build/test/docs system
 - Human-readable error messages and linter/formatter

Rust in the Real World

- ❖ Created in 2006, sponsored by Mozilla in 2009
 - Didn't gain much adoption until version 1.0 in 2015
 - Named the “most admired programming language” from 2016—2025 in the StackOverflow developer survey
- ❖ Who is using Rust?
 - Linux Kernel
 - [AWS Lambda](#) (trillions of requests/mo)
 - [Cloudflare](#) web proxy (3 trillion requests/mo)
 - [Firefox](#) (200M active users/mo)
 - [Discord](#), [Dropbox](#), [Meta](#), [Google](#), [Microsoft](#), and more

Rust: Hello World!

See `hello.rs`

```
fn main() {  
    let name : String = std::env::args().nth(1)  
        .expect("Did not provide name");  
    println!("Hello, {name}!");  
}
```

```
amberhu@rocky-wsl:examples$ rustc hello.rs  
amberhu@rocky-wsl:examples$ ./hello Amber  
Hello, Amber!  
amberhu@rocky-wsl:examples$ ./hello  
  
thread 'main' (86215) panicked at hello.rs:5:10:  
Did not provide name  
note: run with `RUST_BACKTRACE=1` environment variable to  
display a backtrace
```

A panic is an error that crashes the program

Lecture Overview

- ❖ Why is C/C++ difficult?
- ❖ Rust programming language
- ❖ **C/C++ vs. Rust**
 - Tools
 - Defaults
 - Memory safety
 - Type safety
 - Race conditions

C/C++: Tools

- ❖ Importing libraries is difficult
 - No centralized package ecosystem (*e.g.*, `pip` for Python)
 - Must download the source files and compile it yourself, or...
 - Hope that there's a binary compatible with your platform
 - No standard tool to generate documentation

- ❖ No standard tools
 - Many compilers, testing frameworks, and documentation tools
 - Usually not portable! Need different tools for different platforms

- ❖ Error messages are hard to interpret
 - Linking errors
 - C++ template errors are notoriously obtuse

Rust: Tools

- ❖ One toolset, almost any platform
 - rustup (Installs rustc and cargo for your platform)
 - rustc \approx gcc
 - cargo (Manages build pipeline and packages)
 - cargo build \approx make
 - cargo test \approx ./test_suite
 - cargo doc \approx doxygen, javadoc
 - cargo add package \approx pip install package
 - cargo run \approx make bin && ./bin
 - cargo run --example foo = Runs `examples/foo.rs`

- ❖ Readable error messages
 - Error message often suggests a possible fix!

Using Packages: cargo

Type inferred as `DateTime<Local>`
Easy to read and write, like Python,
but statically typed like Java/C++

See `time.rs`

```
use chrono::Local;

fn main() {
    let time = Local::now();
    println!("It is now {}", time.format("%H:%M"));
}
```

```
amberhu@rocky-wsl:examples$ cargo run --example time
  Compiling cse333-rust-demo v0.1.0 (~/)
error[E0432]: unresolved import `chrono`
  --> examples/time.rs:1:5
   |
1  | use chrono::Local;
   |     ^^^^^^^ use of unresolved module or unlinked crate `chrono`
   = help: if you wanted to use a crate named `chrono`, use `cargo add chrono` to add it to your `Cargo.toml`
```

For more information about this error, try ``rustc --explain E0432``.

C/C++: Weird Defaults

- ❖ `char` type is 1 byte, always
 - Designed to support Latin character sets (*e.g.*, ASCII)
 - Websites in 2026: 99% Unicode (UTF-8), 1% ASCII-based
 - UTF-8 is variable length: each character is 1-4 bytes
 - The n^{th} character in a UTF-8 string is not necessarily the $(n-1)^{\text{th}}$ byte!
- ❖ All functions visible in global namespace
 - Marking “`static`” makes it invisible outside current file
 - Helper functions need a `_priv.h` to use across multiple files
- ❖ Mutable (non-const)
 - Easy to accidentally mutate a variable without noticing
 - `string` greeting = `hello.append(name);`

Rust: Immutable by Default

See [greet.rs](#)

```
fn main() {
    let greeting = "你好,";
    let name : String = std::env::args().nth(1)
        .expect("Did not provide name");
    println!("{greeting} {name}!");
    greeting = "再見,";
    println!("{greeting} {name}!");
}
```

```
error[E0384]: cannot assign twice to immutable variable `greeting`
--> examples/greet.rs:10:5
   |
 4 |     let greeting = "你好,"; // hmmm
   |     ----- first assignment to `greeting`
...
10 |     greeting = "再見,";
   |     ^^^^^^^^^^^^^^^^^^^ cannot assign twice to immutable variable

help: consider making this binding mutable

 4 |     let mut greeting = "你好,"; // hmmm
   |     +++

For more information about this error, try `rustc --explain E0384`.
```

Rust: Better Defaults

- ❖ `char` type is Unicode (superset of ASCII)
 - Strings are encoded in UTF-8
- ❖ Variables are immutable by default
 - Must declare variables as `mut` to be mutable
- ❖ Namespaces are restricted by file
 - Functions are private by default, must declare as `pub` to be public
 - `use` declarations are similar to Python imports

Rust: References, Not Pointers

- ❖ In “safe” Rust, you don’t directly manipulate pointers
 - Rust references are like C++ references, but you can rebind them
 - Written as `&Type` or `&mut Type`
 - Rust references have the following guarantees
 - They cannot be null
 - They refer to a living variable (*i.e.*, it hasn’t been deallocated)
- ❖ However, there is also “unsafe” Rust
 - The compiler allows you to do things it would normally ban
 - You must explicitly use the `unsafe` keyword
 - Makes you really think twice!
 - Pointers do exist in Rust, but they are treated as unsafe
- ❖ See `borrow.rs`

C/C++: Type (Un)safety

- ❖ Easy to accidentally reinterpret bits
 - `char c = 'A'; cout << (c+2) << endl;` ⇒ 67
 - `int32_t x = -1; printf("%u\n", x);` ⇒ 4294967295
- ❖ Arithmetic overflow
 - `uint8_t x = 255; x++; printf("%d\n", x);` ⇒ 0
- ❖ No guarantee what a `void*` points to
 - Could be an `int32_t`, stack-allocated `vector`, `char []` ...
 - Might not even be a pointer!
 - *e.g.*, storing integer values in `LinkedList` in HW2/3
 - C++ templates tried to fix this, but system call code is written in C

Rust: Type Safety

- ❖ All pointer manipulation and bit manipulation is unsafe
 - Requires use of `unsafe` keyword
- ❖ Arithmetic overflow will cause a panic
 - Useful for testing, disabled in production for speed
- ❖ Safer, readable error handling
 - `Result<T, E>` is either `Ok` with type `T` or `Err` with type `E`
 - If the current fn also returns a `Result`, use the `?` operator
 - `Ok(val) => val`, `Err(msg) => return Err(msg)`
 - Unhandled errors will result in a compile-time warning
 - See `result.rs`

C/C++: Memory Errors

- ❖ Sometimes causes a crash
 - Dereferencing NULL
- ❖ Sometimes silently causes problems
 - Read from uninitialized memory
 - Writing one past the end of an array
- ❖ Sometimes causes security vulnerabilities!
 - Buffer overflow
 - Use after free
- ❖ Memory leaks
 - C++11 tried to fix this with smart pointers, but adoption is slow

Rust: Memory Safety

- ❖ Buffer overflows are impossible
 - Out of bounds indexing causes a panic at runtime
- ❖ Read from uninitialized memory is impossible
 - All data must be initialized before reading
- ❖ Memory leaks are almost impossible
 - Data gets destructed (Dropped) when it goes out of scope
 - Still have to watch out for cycles (think `weak_ptr`)
- ❖ See [memory.rs](#)

C/C++: Data Races

- ❖ Data races occur when multiple threads share memory that *could* be modified
 - 2 threads with const pointers?
 - OK
 - 2 thread with mutable pointers?
 - Compiles, with data race
 - 1 thread with a mutable pointer, 1 thread with a const pointer?
 - Compiles, with data race

- ❖ We had to remember to use mutex locks to synchronize
 - Easy to accidentally forget to lock or unlock!

Rust: No Data Races

- ❖ Safe Rust eliminates all data races
 - Borrow checker prevents two threads from sharing memory if it could be mutated
 - 1 mutable reference: OK
 - 1 mutable reference and 1+ other references: **Does not compile!**
 - Borrow checker rules apply in single threaded code as well
- ❖ Synchronization primitives still available (*e.g.*, `Mutex<T>`)
 - Cannot mutate the data without calling `.lock()` on `Mutex`
 - Lock automatically released when it goes out of scope!
- ❖ See `threads.rs`

Want to Learn More?

- ❖ [Rust by Example](#)

- ❖ [Rust Book](#)
 - Available offline with `rustup doc --book`
 - [Brown University's version](#) has interactive quizzes
 - [Final project](#): build a multi-threaded web server (sound familiar?)
 - In some ways harder than HW4
 - Rust's borrow checker rules take time to get used to
 - In some ways easier: compiler **guarantees** memory and thread safety

- ❖ CSE 334: Modern Concurrency
 - New course, taught for the first time in 26wi as [493L](#)
 - Intended to be the canonical “Rust course”
