

## CSE 341: Programming Languages

Spring 2006

Lecture 21 — Exceptions & Continuations

CSE 341 Spring 2006, Lecture 21

1

### Exceptions in Scheme

Recall exceptions in Java, ML: Transfer control to nearest *dynamically scoped* exception handler (i.e., nearest on “call stack”).

Transfer control: Forget what you’re doing. Result of entire program is now result of the handle (catch) in the “call stack” that existed when the handler was reached.

Scheme has a *more powerful* concept that can be a little less convenient for exceptions:

- You explicitly indicate what “handler” (*continuation*) to transfer control to.
- You do the transfer via a function application (that does not have function-application semantics)
- The continuation does not even have to be on the “call stack” when it’s transferred to!

3

### Control Flow

$(+ (f\ 2\ 3) (- (f\ 4\ (*\ 5\ 6))\ 7))$

Calls: always more to do ... (until the end)

$(f\ 2\ 3)$  then  $(*\ 5\ 6)$  then  $(f\ 4\ 30)$  then  $(- \text{ whatever } 7)$  then ...

Returns: What next? There’s always somebody waiting ...

e.g. waiting for  $(f\ 4\ (*\ 5\ 6))$ , we have  $(\lambda (x) (+ (f\ 2\ 3) (- x\ 7)))$

$((\lambda (x) (+ (f\ 2\ 3) (- x\ 7))) (f\ 4\ (*\ 5\ 6)))$

Defn: what-to-do-next after the call  $(f\ 4\ (*\ 5\ 6))$  is its *continuation*

Scheme provides access to continuations!

2

### Continuations for exceptions

Plan:

- Using continuations for exceptions (More details later, time permitting)

Syntax:

- $(\text{let/cc } k\ e1)$  : in  $e1$ , bind  $k$  to “current continuation” (basically, the point immediately after the `let/cc`) then eval  $e1$
- $(k\ e2)$ : “invoke” continuation bound to  $k$ , passing value  $e2$ , in lieu of the value of  $e1$  (now aborted)

Exception idiom:

- Instead of handler, use `let/cc`
- Pass an appropriate function that invokes  $k$  to any function that needs to “raise”
