Dynamic Dispatch Precisely, and Manually in Racket

Zach Tatlock
Winter 2018

## Dynamic dispatch

## Dynamic dispatch

- Also known as late binding or virtual methods
- Call self.m2() in method m1 defined in class C can resolve to a method m 2 defined in a subclass of C
- Most unique characteristic of OOP

Need to define the semantics of method lookup as carefully as we defined variable lookup for our PLs

## Review: variable lookup

Rules for "looking things up" is a key part of PL semantics

- ML: Look up variables in the appropriate environment
- Lexical scope for closures
- Field names (for records) are different: not variables
- Racket: Like ML plus let, letrec
- Ruby:
- Local variables and blocks mostly like ML and Racket
- But also have instance variables, class variables, methods (all more like record fields)
- Look up in terms of self, which is special

## Using self

- self maps to some "current" object
- Look up instance variable @x using object bound to self
- Look up class variables @@x using object bound to self.class
- Look up methods...

## Ruby method lookup

The semantics for method calls also known as message sends
e0.m (e1,...,en)

1. Evaluate e $0, e 1, \ldots$, en to objects obj $0, \operatorname{obj} 1, \ldots, o b j n$

- As usual, may involve looking up self, variables, fields, etc.

2. Let C be the class of obj0 (every object has a class)
3. If $m$ is defined in $C$, pick that method, else recur with the superclass of $C$ unless $C$ is already Object

- If no mis found, call method_missing instead
- Definition of method_missing in Object raises an error

4. Evaluate body of method picked:

- With formal arguments bound to obj1, ..., objn
- With self bound to obj0 -- this implements dynamic dispatch!

Note: Step (3) complicated by mixins: will revise definition later

## Punch-line again

$$
\text { e0.m (e1, ...,en })
$$

To implement dynamic dispatch, evaluate the method body with self mapping to the receiver (result of e0)

- That way, any self calls in body of m use the receiver's class,
- Not necessarily the class that defined $m$
- This much is the same in Ruby, Java, C\#, Smalltalk, etc.

## Comments on dynamic dispatch

- This is why distFromOrigin2 worked in PolarPoint
- More complicated than the rules for closures
- Have to treat self specially
- May seem simpler only if you learned it first
- Complicated does not necessarily mean inferior or superior

## Static overloading

In Java/C\#/C++, method-lookup rules are similar, but more complicated because > 1 methods in a class can have same name

- Java/C/C++: Overriding only when number/types of arguments the same
- Ruby: same-method-name always overriding

Pick the "best one" using the static (!) types of the arguments

- Complicated rules for "best"
- Type-checking error if there is no "best"

Relies fundamentally on type-checking rules

- Ruby has none

## A simple example, part 1

In ML (and other languages), closures are closed

```
fun even x = if x=0 then true else odd (x-1)
and odd }x=\mp@code{if x=0 then false else even (x-1)
```

So we can shadow odd, but any call to the closure bound to odd above will "do what we expect"

- Does not matter if we shadow even or not

```
(* does not change odd - too bad; this would
    improve it *)
fun even x = (x mod 2)=0
(* does not change odd - good thing; this would
    break it *)
fun even x = false
```

## A simple example, part 2

In Ruby (and other OOP languages), subclasses can change the behavior of methods they do not override

```
class A
    def even x
        if }x==0\mathrm{ then true else odd (x-1) end
    end
    def odd x
        if x==0 then false else even (x-1) end
    end
end
class B < A # improves odd in B objects
    def even x ; x % 2 == 0 end
end
class C < A # breaks odd in C objects
    def even x ; false end
end
```

## The OOP trade-off

Any method that makes calls to overridable methods can have its behavior changed in subclasses even if it is not overridden

- Maybe on purpose, maybe by mistake
- Observable behavior includes calls-to-overridable methods
- So harder to reason about "the code you're looking at"
- Can avoid by disallowing overriding
- "private" or "final" methods
- So easier for subclasses to affect behavior without copying code
- Provided method in superclass is not modified later

## Manual dynamic dispatch

Now: Write Racket code with little more than pairs and functions that acts like objects with dynamic dispatch

Why do this?

- (Racket actually has classes and objects available)
- Demonstrates how one language's semantics is an idiom in another language
- Understand dynamic dispatch better by coding it up
- Roughly how an interpreter/compiler might

Analogy: Earlier optional material encoding higher-order functions using objects and explicit environments

## Our approach

Many ways to do it; our code does this:

- An "object" has a list of field pairs and a list of method pairs (struct obj (fields methods))
- Field-list element example:
(mcons 'x 17)
- Method-list element example:
(cons 'get-x (lambda (self args) ...))

Notes:

- Lists sufficient but not efficient
- Not class-based: object has a list of methods, not a class that has a list of methods [could do it that way instead]
- Key trick is lambdas taking an extra self argument
- All "regular" arguments put in a list args for simplicity

## A point object bound to $\mathbf{x}$

## Key helper functions

Now define plain Racket functions to get field, set field, call method

```
(define (assoc-m v xs)
    ...) ; assoc for list of mutable pairs
(define (get obj fld)
    (let ([pr (assoc-m fld (obj-fields obj))]))
        (if pr (mcdr pr) (error ...))))
(define (set obj fld v)
    (let ([pr (assoc-m fld (obj-fields obj))]))
        (if pr (set-mcdr! pr v) (error ...))))
(define (send obj msg . args)
    (let ([pr (assoc msg (obj-methods obj))]))
        (if pr ((cdr pr) obj args) (error ...))))
```

(send $x$ 'distToOrigin)

## Evaluate body of $\lambda$ (self args)... with self bound to entire object (and args bound to ' ())

$\lambda$ (self args)...
$\lambda$ (self args)...

## Constructing points

- Plain-old Racket function can take initial field values and build a point object
- Use functions get, set, and send on result and in "methods"
- Call to self: (send self 'm ...)
- Method arguments in args list
(define (make-point _x _y)
(obj
(list (mcons 'x _x)
$($ mcons 'y _y) )
(list (cons 'get-x ( $\lambda(s e l f$ args) (get self 'x)))
(cons 'get-y ( $\lambda$ (self args) (get self 'y)))
(cons 'set-x ( $\lambda(s e l f$ args) (...)))
(cons 'set-y ( $\lambda($ self args) (...)))
(cons 'distToOrigin ( $\lambda(s e l f$ args)(...))))))

## "Subclassing"

- Can use make-point to write make-color-point or make-polar-point functions (see code)
- Build a new object using fields and methods from "super" "constructor"
- Add new or overriding methods to the beginning of the list
- send will find the first matching method
- Since send passes the entire receiver for self, dynamic dispatch works as desired

## Why not ML?

- We were wise not to try this in ML!
- ML's type system does not have subtyping for declaring a polarpoint type that "is also a" point type
- Workarounds possible (e.g., one type for all objects)
- Still no good type for those self arguments to functions
- Need quite sophisticated type systems to support dynamic dispatch if it is not built into the language
- In fairness, languages with subtyping but not generics make it analogously awkward to write generic code
