CSE341: Programming Languages

Lecture 4
Records, Datatypes, Case Expressions

Brett Wortzman

Summer 2019

Slides originally created by Dan Grossman

Five different things

1. Syntax: How do you write language constructs?

2. Semantics: What do programs mean? (Evaluation rules)

3. Idioms: What are typical patterns for using language features to express your computation?

4. Libraries: What facilities does the language (or a well-known project) provide "standard"? (E.g., file access, data structures)

5. Tools: What do language implementations provide to make your job easier? (E.g., REPL, debugger, code formatter, …)

    –   Not actually part of the language

These are 5 separate issues
   – In practice, all are essential for good programmers
   – Many people confuse them, but shouldn't

Our Focus

This course focuses on semantics and idioms

- Syntax is usually uninteresting
  - A fact to learn, like "The American Civil War ended in 1865"
  - People obsess over subjective preferences

- Libraries and tools crucial, but often learn new ones "on the job"
  - We are learning semantics and how to use that knowledge to understand all software and employ appropriate idioms
  - By avoiding most libraries/tools, our languages may look "silly" but so would *any* language used this way

How to build bigger types

- Already know:
  - Have various *base types* like `int bool unit char`

  - Ways to build (nested) *compound types*: tuples, lists, options

- Coming soon: more ways to build compound types

- First: 3 most important type building blocks in *any* language
  - "Each of": A `t` value contains *values of each of* `t1 t2` … `tn`
  - "One of": A `t` value contains *values of one of* `t1 t2` … `tn`
  - "Self reference": A `t` value can refer to other `t` values

  Remarkable: A lot of data can be described with just these building blocks

  Note: These are not the common names for these concepts

Examples

- Tuples build each-of types
  - `int * bool` contains an `int` *and* a `bool`

- Options build one-of types
  - `int option` contains an `int` *or* it contains no data

- Lists use all three building blocks
  - `int list` contains an `int` *and* another `int list` *or* it contains no data

- And of course we can nest compound types
  - `((int * int) option * (int list list)) option`

Rest of this Lecture

- Another way to build each-of types in ML
    - *Records*: have named *fields*
    - Connection to tuples and idea of *syntactic sugar*

- A way to build and use our own one-of types in ML
    - For example, a type that contains an `int` or a `string`
    - Will lead to *pattern-matching*, one of ML's coolest and strangest-to-Java-programmers features

- Later in course: How OOP does one-of types
    - Key contrast with procedural and functional programming

Records

Record values have fields (any name) holding values

$$\{\texttt{f1 = v1, ..., fn = vn}\}$$

Record types have fields (and name) holding types

$$\{\texttt{f1 : t1, ..., fn : tn}\}$$

The order of fields in a record value or type never matters
- REPL alphabetizes fields just for consistency

Building records:

$$\{\texttt{f1 = e1, ..., fn = en}\}$$

Accessing components:

$$\texttt{\#myfieldname e}$$

(Evaluation rules and type-checking as expected)

Example

> `{name = "Matai", id = 4 - 3}`

Evaluates to

> `{id = 1, name = "Matai"}`

And has type

> `{id : int, name : string}`

If some expression such as a variable `x` has this type, then get
fields with: `#id x`   `#name x`

Note we did not have to declare any record types
- – The same program could also make a
    `{id=true,ego=false}` of type `{id:bool,ego:bool}`

By name vs. by position

- Little difference between `(4,7,9)` and `{f=4,g=7,h=9}`
  - Tuples a little shorter
  - Records a little easier to remember "what is where"
  - Generally a matter of taste, but for many (6? 8? 12?) fields, a record is usually a better choice

- A common decision for a construct's syntax is whether to refer to things *by position* (as in tuples) or *by some (field) name* (as with records)
  - A common hybrid is like with Java method arguments (and ML functions as used so far):
    - Caller uses *position*
    - Callee uses *variables*
    - Could totally do it differently; some languages have

The truth about tuples

Previous lecture gave tuples syntax, type-checking rules, and evaluation rules

But we could have done this instead:
- Tuple syntax is just a different way to write certain records
- `(e1,…,en)` is another way of writing `{1=e1,…,n=en}`
- `t1*…*tn` is another way of writing `{1:t1,…,n:tn}`
- In other words, records with field names 1, 2, …

In fact, this is how ML actually defines tuples
- Other than special syntax in programs and printing, they don't exist
- You really can write `{1=4,2=7,3=9}`, but it's bad style

Syntactic sugar

"Tuples are just syntactic sugar for
records with fields named 1, 2, … n"

- *Syntactic*: Can describe the semantics entirely by the corresponding record syntax

- *Sugar*: They make the language sweeter ☺

Will see many more examples of syntactic sugar
  – They simplify *understanding* the language
  – They simplify *implementing* the language

  Why? Because there are fewer semantics to worry about even though we have the syntactic convenience of tuples

Another example we saw: `andalso` and `orelse` vs. `if then else`

Datatype bindings

A "strange" (?) and totally awesome (!) way to make one-of types:

- A `datatype` binding

```
datatype mytype = TwoInts of int * int
                | Str of string
                | Pizza
```

- Adds a new type `mytype` to the environment
- Adds *constructors* to the environment: `TwoInts`, `Str`, and `Pizza`
- A constructor is (among other things), a function that makes values of the new type (or is a value of the new type):
  - `TwoInts : int * int -> mytype`
  - `Str : string -> mytype`
  - `Pizza : mytype`

The values we make

```
datatype mytype = TwoInts of int * int
                | Str of string
                | Pizza
```

- Any value of type `mytype` is made from *one of* the constructors
- The value contains:
  - A "tag" for "which constructor" (e.g., `TwoInts`)
  - The corresponding data (e.g., `(7,9)`)
- Examples:
  - `TwoInts(3+4,5+4)` evaluates to `TwoInts(7,9)`
  - `Str(if true then "hi" else "bye")` evaluates to `Str("hi")`
  - `Pizza` is a value

Using them

So we know how to *build* datatype values; need to *access* them

There are *two* aspects to accessing a datatype value
1. Check what *variant* it is (what constructor made it)
2. Extract the *data* (if that variant has any)

Notice how our other one-of types used functions for this:
- `null` and `isSome` check variants
- `hd`, `tl`, and `valOf` extract data (raise exception on wrong variant)

ML *could* have done the same for datatype bindings
  – For example, functions like "isStr" and "getStrData"
  – Instead it did something better

Case

ML combines the two aspects of accessing a one-of value with a *case expression* and *pattern-matching*

- – Pattern-matching much more general/powerful (Lecture 5)

Example:

```
fun f x = (* f has type mytype -> int *)
    case x of
        Pizza => 3
      | TwoInts(i1,i2) => i1+i2
      | Str s => String.size s
```

- A multi-branch conditional to pick branch based on variant
- Extracts data and binds to variables local to that branch
- Type-checking: all branches must have same type
- Evaluation: evaluate between **case** … **of** and the right branch

Patterns

In general the syntax is:

```
case e0 of
      p1 => e1
    | p2 => e2
      …
    | pn => en
```

For today, each *pattern* is a constructor name followed by the right number of variables (i.e., `C` or `C x` or `C(x,y)` or …)

- Syntactically most patterns (all today) look like expressions
- But patterns are not expressions
  - We do not evaluate them
  - We see if the result of `e0` *matches* them

Why this way is better

0. You can use pattern-matching to write your own testing and data-extractions functions if you must
    –   But do not do that on your homework

1. You cannot forget a case (inexhaustive pattern-match warning)

2. You cannot duplicate a case (a type-checking error)

3. You will not forget to test the variant correctly and get an exception (like `hd []`)

4. Pattern-matching can be generalized and made more powerful, leading to elegant and concise code
