Section 10
Mixins & Subclasses

Spring 2020
Dispatch Overview

Dispatch is the runtime procedure for looking up which function to call based on the parameters given:

- Ruby (and Java) use Single Dispatch on the implicit `self` (or “this”) parameter
  - Uses runtime class of `self` to lookup the method when a call is made
  - This is what you learned in CSE 143

- Double Dispatch uses the runtime classes of both `self` and a single method parameter
  - Ruby/Java do not have this, but we can emulate it
  - This is what you will do in HW7

- You can dispatch on any number of the parameters and the general term for this is Multiple Dispatch or Multimethods
Emulating Double Dispatch

• To emulate double dispatch in Ruby (on HW7) just use the built-in single dispatch procedure **twice!**
  • Have the principal method immediately call another method on its *first parameter*, passing `self` as an argument
  • The second call will implicitly know the class of the `self` parameter
  • It will also know the class of the *first parameter* of the principal method, because of **Single Dispatch**
• There are other ways to emulate double dispatch
  • Found as an idiom in SML by using case expressions
Double Dispatch Example: RPS

- Suppose we wanted to code up a game of “Rock-Paper-Scissors”:
  - A game that is played in rounds with 2 players.
  - Each player gets to pick a weapon: one of “Rock”, “Paper”, or “Scissors”.
- Each combination results in a winner/loser (except when both are the same):
  - Rock beats Scissors
  - Paper beats Rock
  - Scissors beats Paper
**Double Dispatch Example: RPS**

- **What are the different combinations of games?**
  - Player 1 fights Player 2 with a tool, and Player 2 responds, which determines the outcome.

<table>
<thead>
<tr>
<th></th>
<th>Rock</th>
<th>Paper</th>
<th>Scissors</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Rock</strong></td>
<td>Tie</td>
<td>Paper wins</td>
<td>Rock wins</td>
</tr>
<tr>
<td><strong>Paper</strong></td>
<td>Paper wins</td>
<td>Tie</td>
<td>Scissor wins</td>
</tr>
<tr>
<td><strong>Scissors</strong></td>
<td>Rock wins</td>
<td>Scissor wins</td>
<td>Tie</td>
</tr>
</tbody>
</table>
Double Dispatch Example: RPS

- How could we represent this in an OOP way?
  - How does “Class 1” fight “Class 2”? How do we encode the “tool”? How do we encode the “outcome”?

<table>
<thead>
<tr>
<th></th>
<th>Class 1</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Rock</strong></td>
<td>Tie</td>
<td>Paper wins</td>
<td>Rock wins</td>
</tr>
<tr>
<td><strong>Paper</strong></td>
<td>Paper wins</td>
<td>Tie</td>
<td>Scissor wins</td>
</tr>
<tr>
<td><strong>Scissors</strong></td>
<td>Rock wins</td>
<td>Scissor wins</td>
<td>Tie</td>
</tr>
</tbody>
</table>
Double Dispatch Exercise:

What’s the table? (hint, it’s 2x2)

class A
def f x
    x.fWithA self
end
def fWithA a
    "(a, a) case"
end
def fWithB b
    "(b, a) case"
end
end
class B
def f x
    x.fWithB self
end
def fWithA a
    "(a, b) case"
end
def fWithB b
    "(b, b) case"
end
end
**Double Dispatch Exercise:**

What’s the table? (hint, it’s 2x2)

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>A</strong></td>
<td>(a,a) case</td>
<td>(b,a) case</td>
</tr>
<tr>
<td><strong>B</strong></td>
<td>(a,b) case</td>
<td>(b,b) case</td>
</tr>
</tbody>
</table>
Extending RPS

What if we wanted to extend our game to add an action to convert each of the tools to strings?

- What would we have to change so that we could still play this game, but with another action?

<table>
<thead>
<tr>
<th></th>
<th>Rock</th>
<th>Paper</th>
<th>Scissors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rock</td>
<td>Tie</td>
<td>Paper wins</td>
<td>Rock wins</td>
</tr>
<tr>
<td>Paper</td>
<td>Paper wins</td>
<td>Tie</td>
<td>Scissor wins</td>
</tr>
<tr>
<td>Scissors</td>
<td>Rock wins</td>
<td>Scissor wins</td>
<td>Tie</td>
</tr>
<tr>
<td>toString*</td>
<td>Rock</td>
<td>Paper</td>
<td>Scissors</td>
</tr>
</tbody>
</table>

*note: not a Class, but a method, because it only operates on 1 class, not 2.*
Mixins

- Collection of methods
  - Unlike class, you cannot instantiate it
- Can include any number of mixins
- Provides powerful extensions to the class with little cost
**Mixins**

- It’s just “copy and paste the code into the class”
  - Will override existing code
  - Have access to instance functions
  - Have access to instance variables
Mixins Example

```ruby
module Doubler
  def double
    self + self # assume included in classes w/
    + end
  end
end

class String
  include Doubler
end

class AnotherPt
  attr_accessor :x,
  :y include Doubler
  def + other
    ans = AnotherPt.new
    ans.x = self.x +
    other.x  ans.y = self.y
    + other.y  ans
  end
end
```
Method Lookup Rules

1. Current class
2. Current class’s mixins
   a. Latest included mixin
   b. ..... 
   c. Earliest included mixin
3. Current class’s super class
4. Current class’s super class’s mixins
5. .....
**Comparable**

It provides you methods to compute

\(<, >, ==, !=, >=, <=\)

What’s needed?

- Define function \(\leq\equiv\) (spaceship operator)
  - Return negative, 0 or positive number

*Very similar to Java Comparable interface which requires compareTo*
Enumerable

It provides you methods to iterate over the object
   -> supports map, find!

What’s needed?

• Define function \texttt{each}
  • \texttt{each} will either call each of other object or will yield result

\textit{Very similar to Java Iterable interface}
Java Subtyping

Arrays should work just like records in terms of depth subtyping

- But in Java, if \( t_1 <: t_2 \), then \( t_1[] <: t_2[] \)
- So this code type-checks, surprisingly

```java
class Point { ... }
class ColorPoint extends Point { ... }

void m1(Point[] pt_arr) {
    pt_arr[0] = new Point(3,4);
}
String m2(int x) {
    ColorPoint[] cpt_arr = new ColorPoint[x];
    for (int i=0; i < x; i++)
        cpt_arr[i] = new ColorPoint(0,0,"green");
    m1(cpt_arr); // !
    return cpt_arr[0].color; // !
}
```
Why?

More flexible type system allows more programs but prevents fewer errors
- Seemed especially important before Java/C# had generics

**Good news:** despite this “inappropriate” depth subtyping
- e.color will never fail due to there being no color field
- Array reads e1[e2] always return a (subtype of) t if e1 is a t[]

**Bad news:** to get the good news
- \( e1[e2] = e3 \) can fail even if \( e1 \) has type \( t[] \) and \( e3 \) has type \( t \)
- Array stores check the run-time class of e1's elements and do not allow storing a supertype
- No type-system help to avoid such bugs / performance cost
