

Relational Algebra, Relational Calculus, Datalog

Past Midterm problems

1) Schema: R(A, B), S(C, D, E), T(F, G); Spring, 2011

Write Relational Algebra Plan for the SQL query below. Your answer should be a tree representing the relational algebra plan.

```
SELECT R.B, S.E, sum(T.G)
FROM R, S, T
WHERE R.A = S.C and S.D = T.F and T.H > 55
GROUP BY R.B, S.E
```

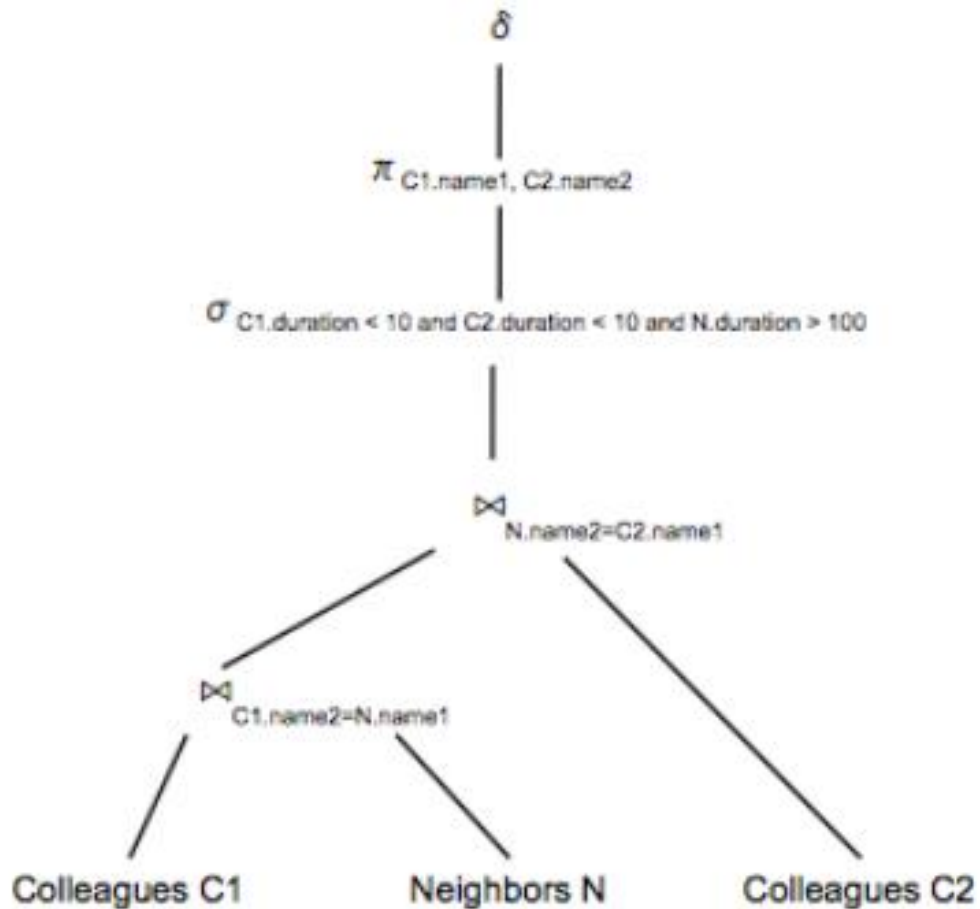

2) Consider the following database schema (Fall 2011)

Neighbors(name1,name2,duration), Colleagues(name1,name2,duration)

(a) Write a Relational Algebra Plan for the SQL query below. Your answer can be in the form of an expression or a tree, whichever you prefer:

```
SELECT DISTINCT C1.name1, C2.name2
FROM Colleagues C1, Neighbors N, Colleagues C2
WHERE C1.name2 = N.name1
AND N.name2 = C2.name1
AND C1.duration < 10
AND C2.duration < 10
AND N.duration > 100
```

(b) Write a Datalog query that returns all neighbors who do not have any colleagues in common.

Solution: $\text{NonAnswers}(n1, n2) \text{:- Neighbors}(n1, n2, -), \text{Colleagues}(n1, c, -), \text{Colleagues}(n2, c, -)$
 $\text{A}(n1, n2) \text{:- Neighbors}(n1, n2, -), \text{NOT NonAnswer}(n1, n2)$

(c) **relational calculus** queries

- Find all people who have a neighbor that has a colleague.

$$A(x) = \exists y. \exists z. \text{Neighbors}(x, y, -) \wedge \text{Colleagues}(y, z, -)$$

- Find all people who have only neighbors that are also their colleagues.

$$A(x) = \text{Neighbors}(x, -, -) \wedge (\forall y. \text{Neighbors}(x, y, -) \Rightarrow \text{Colleagues}(x, y, -))$$

- Find all people who have only neighbors that have at least one colleague.

$$A(x) = \text{Neighbors}(x, -, -) \wedge (\forall y. \text{Neighbors}(x, y, -) \Rightarrow \exists z. \text{Colleagues}(y, z, -))$$

3. (Spring '11) Consider a database consisting of the following two relations:

$\text{Person}(\text{pid}, \text{name})$
 $\text{Trusts}(\text{pid1}, \text{pid2})$

Answer each question below by writing a query in non-recursive datalog with negation. Your answer should return the person id and the name. For example, if the question were *find people who trust everyone except themselves* then your answer would be:

$S(p) \quad \text{:- Person}(p, n), \text{Person}(q, m), \text{not Trusts}(p, q), p \neq q$
 $A(p, n) \quad \text{:- Person}(p, n), \text{not } S(p)$

1. A *loner* is a person who trusts no-one but himself. Return all loners.

Answer (write a datalog query):

$\text{NA}(p) \quad \text{:- Trusts}(p, x), p \neq x$
 $\text{A}(p, n) \quad \text{:- Person}(p, n), \text{not NA}(p)$

2. A *loyal* is a person who trusts only those who trust him. Return all loyals.

$NA(p) \quad :- \text{Trusts}(p,x), \text{ not Trusts}(x,p)$

$A(p,n) \quad :- \text{Person}(p,n), \text{ not } NA(p)$

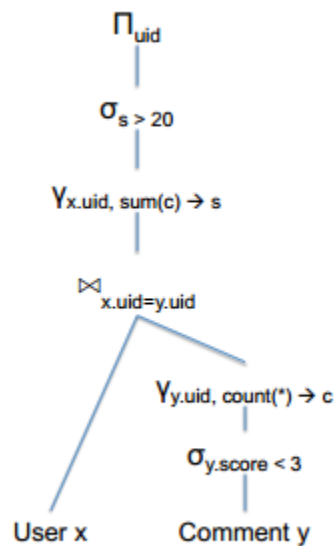

3. A *ruler* is a person who trusts only those who trust only him. Return all rulers.

$NA(p) \quad :- \text{Trusts}(p,x), \text{ Trusts}(x,y), p \neq y$

$A(p,n) \quad :- \text{Person}(p,n), \text{ not } NA(p)$

4.

(10 points) Consider the Relational Algebra expression below:

Write an equivalent SQL query *without* using any subqueries.

```
select x.uid
from Users x, Comment y
where x.uid = y.uid and y.score < 3
group by x.uid
having count(*) > 20
```
