Introduction to Data Management CSE 344

Lecture 20: Introduction to Transactions

Announcements

- Office hour today is canceled
- Webquiz 6 due tonight
- HW6 due on Friday
- Webquiz 7 (final!) due next Wednesday

Data Management Pipeline

Demo (see lec20-transactions-intro.sql)

Challenges

- Want to execute many apps concurrently

 All these apps read and write data to the same DB
- Simple solution: only serve one app at a time – What's the problem?
- Better: multiple operations need to be executed *atomically* over the DB

- Manager: balance budgets among projects
 - Remove \$10k from project A
 - Add \$7k to project B
 - Add \$3k to project C
- CEO: check company's total balance
 SELECT SUM(money) FROM budget;
- This is called a dirty / inconsistent read aka WRITE-READ conflict

- App 1: SELECT inventory FROM products WHERE pid = 1
- App 2: UPDATE products SET inventory = 0 WHERE pid = 1
- App 1: SELECT inventory * price FROM products WHERE pid = 1
- This is known as an unrepeatable read aka READ-WRITE conflict

Account 1 = \$100 Account 2 = \$100 Total = \$200

- App 1:
 - Set Account 1 = \$200
 - Set Account 2 = \$0
- App 2:
 - Set Account 2 = \$200
 - Set Account 1 = \$0

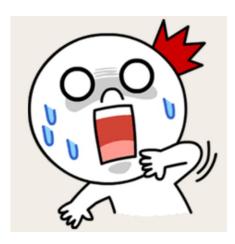

- App 1: Set Account 1 = \$200
- App 2: Set Account 2 = \$200
- App 1: Set Account 2 = \$0
- App 2: Set Account 1 = \$0

- At the end:
 - Total = \$200

- At the end:
 - Total = \$0

This is called the lost update aka WRITE-WRITE conflict CSE 344 - Winter 2016 8

- Buying tickets to the next Bieber concert:
 - Fill up form with your mailing address
 - Put in debit card number
 - Click submit
 - Screen shows money deducted from your account
 - [Your browser crashes]

Changes to the database should be ALL or NOTHING

Transactions

 Collection of statements that are executed atomically (logically speaking)

```
BEGIN TRANSACTION
[SQL statements]
COMMIT or
ROLLBACK (=ABORT)
```

Transactions Demo (see lec20-transactions-intro.sql)

Serial execution

- **Definition**: A SERIAL execution of transactions is one where each transaction is executed one after another.
- Fact: Nothing can go wrong if the DB executes transactions serially.
- **Definition**: A SERIALIZABLE execution of transactions is one that is equivalent to a serial execution

ACID

- Atomic
 - State shows either all the effects of txn, or none of them
- Consistent
 - Txn moves from a state where integrity holds, to another where integrity holds
- Isolated
 - Effect of txns is the same as txns running one after another (i.e., looks like batch mode)
- Durable
 - Once a txn has committed, its effects remain in the database

Atomic

- **Definition**: A transaction is ATOMIC if all its updates must happen or not at all.
- Example: move \$100 from A to B
 - UPDATE accounts SET bal = bal 100
 WHERE acct = A;
 - UPDATE accounts SET bal = bal + 100
 WHERE acct = B;
 - BEGIN TRANSACTION; UPDATE accounts SET bal = bal – 100 WHERE acct = A; UPDATE accounts SET bal = bal + 100 WHERE acct = B; COMMIT; CSE 344 - Winter 2016

Isolated

• **Definition** An execution ensures that txns are isolated, if the effect of each txn is as if it were the only txn running on the system.

Consistent

- Recall: integrity constraints govern how values in tables are related to each other
 - Can be enforced by the DBMS, or ensured by the app
- How consistency is achieved by the app:
 - App programmer ensures that txns only takes a consistent DB state to another consistent state
 - DB makes sure that txns are executed atomically
- Can defer checking the validity of constraints until the end of a transaction

Durable

- A transaction is durable if its effects continue to exist after the transaction and even after the program has terminated
- How? By writing to disk

Rollback transactions

- If the app gets to a state where it cannot complete the transaction successfully, execute ROLLBACK
- The DB returns to the state prior to the transaction
- What are examples of such program states?

ACID

- Atomic
- Consistent
- Isolated
- Durable
- Enjoy this in HW7!
- Note: by default each statement is its own tx
 - Unless auto-commit is off then each statement starts a new tx

Implementation of transactions

- sqlite: single lock for the entire DB
 - http://www.sqlite.org/atomiccommit.html
 - Not true for SQL Server, DB2, etc

SQLite Transactions

- **Step 1**: When txn starts: acquires a read lock (aka shared lock)
- Step 2: When txn writes: acquire a reserved lock
- **Step 3**: When txn commits:
 - First acquire a pending lock: no new read locks allowed
 - Wait until all current read locks are released
 - Acquire an exclusive lock
 - Make updates to DB on disk
 - Commit, release all locks
