IT'S UNSETTLING TO REALIZE HOW QUICKLY DIGITAL RESOURCES CAN DISAPPEAR WITHOUT ONGOING WORK TO MAINTAIN THEM.

<http://xkcd.com/1909/>

# Administrivia

- ❖ Homework 5 due Friday (11/30)
- ❖ Lab 5 due next Friday (12/7)
  
- ❖ **Final Exam:** Wed, Dec. 12 @ 12:30 pm in KNE 120
  - Review Session: Sun, Dec. 9 @ 5:00 pm in EEB 105
  - Cumulative (midterm clobber policy applies)
  - You get TWO double-sided handwritten 8.5×11" cheat sheets
    - Recommended that you reuse or remake your midterm cheat sheet

# Peer Instruction Question

❖ Which allocation strategy and requests remove external fragmentation in this Heap? B3 was the last fulfilled request.

▪ <http://PollEv.com/justinh>

**(A) Best-fit:**

`malloc(50), malloc(50)`

**(B) First-fit:**

`malloc(50), malloc(30)`

**(C) Next-fit:**

`malloc(30), malloc(50)`

**(D) Next-fit:**

`malloc(50), malloc(30)`

# Implicit List: Allocating in a Free Block

❖ Allocating in a free block: *splitting*

- Since allocated space might be smaller than free space, we might want to split the block

Assume `ptr` points to a free block and has unscaled pointer arithmetic

```

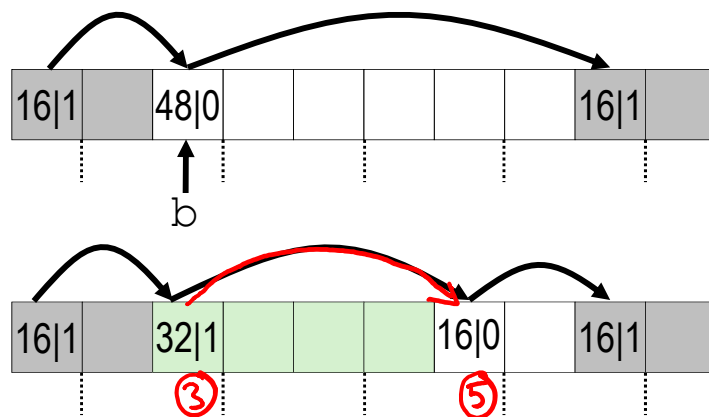

void split(ptr b, int bytes) { // bytes = desired block size
  ① int newsize = ((bytes+15) >> 4) << 4; // round up to multiple of 16
  ② int oldsize = *b; // why not mask out low bit?
  ③ *b = newsize; // initially unallocated
  ④ if (newsize < oldsize)
  ⑤ *(b+newsize) = oldsize - newsize; // set length in remaining
} // part of block (UNSCALED +)
    
```

```

malloc(24):
  ptr b = find(24+8)
  split(b, 24+8)
  allocate(b)
    
```

*↑ sets a=1*

*header*

# Implicit List: Freeing a Block

- ❖ Simplest implementation just clears “allocated” flag
  - `void free(ptr p) { *(p-BOX) &= -2; }`
  - But can lead to “false fragmentation”

# Implicit List: Coalescing with Next

- ❖ Join (*coalesce*) with next block if also free

```

void free(ptr p) {
    ptr b = p - BOX; // p points to payload
    *b &= -2; // b points to block header
    ptr next = b + 32; // clear allocated bit
    if ((*next & 1) == 0) // find next block (UNSCALED +)
        *b += 16 * next; // if next block is not allocated,
                        // add its size to this block
}
    
```

- ❖ How do we coalesce with the *previous* block? *we can't currently*

# Implicit List: Bidirectional Coalescing

- ❖ *Boundary tags* [Knuth73]
  - Replicate header at “bottom” (end) of free blocks
  - Allows us to traverse backwards, but requires extra space
  - Important and general technique!

*Format of allocated and free blocks:*

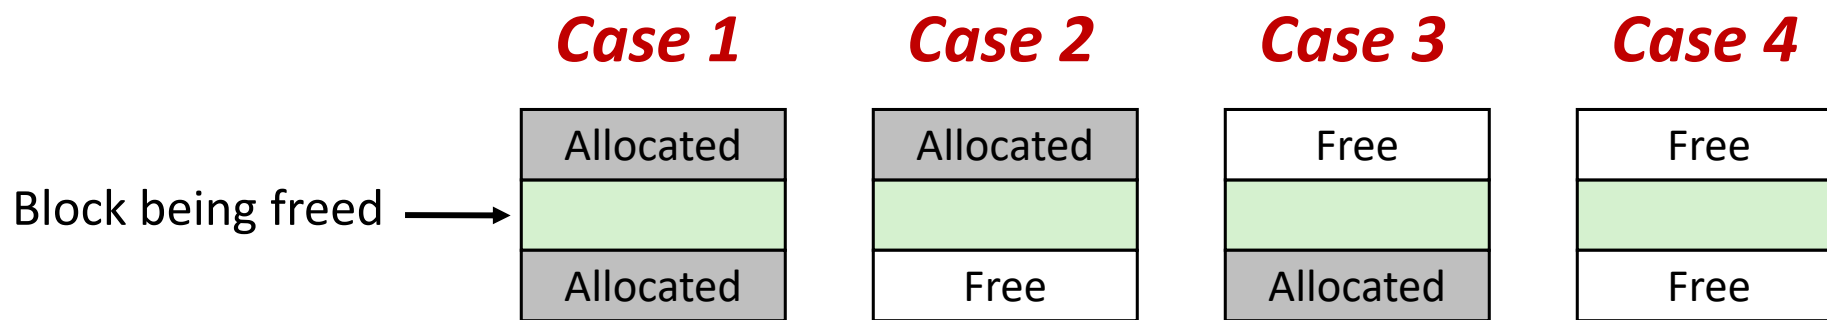

**a = 1:** allocated block

**a = 0:** free block

**size:** block size (in bytes)

**payload:** application data (allocated blocks only)

# Constant Time Coalescing

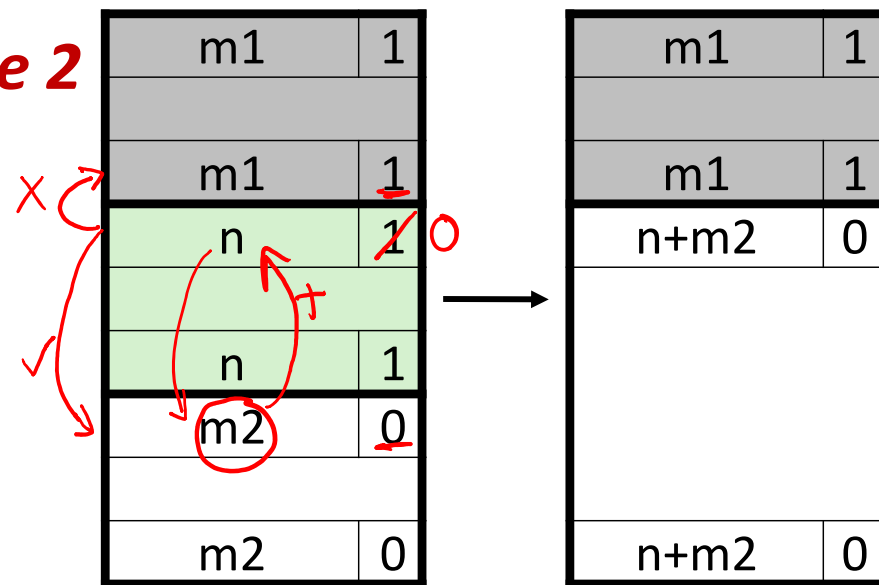

# Constant Time Coalescing

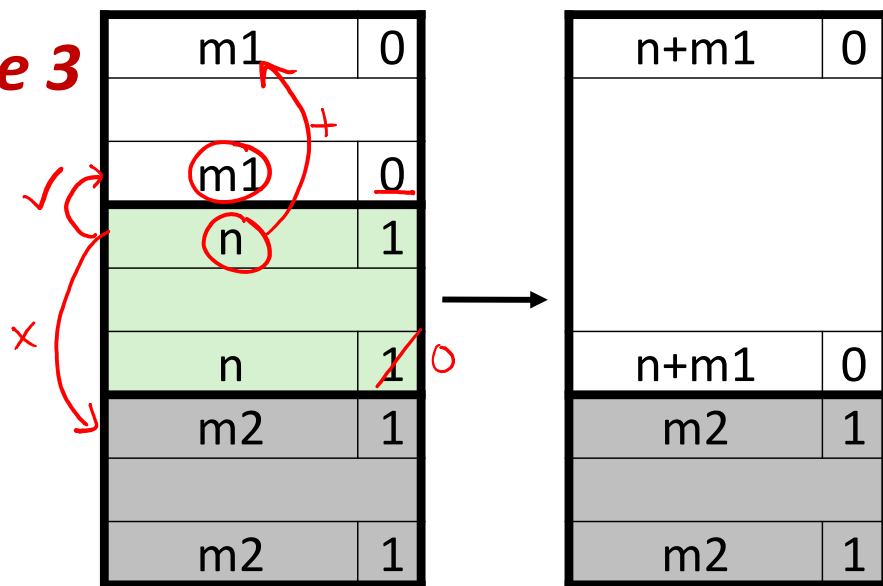

**Case 1**

**Case 2**

**Case 3**

**Case 4**

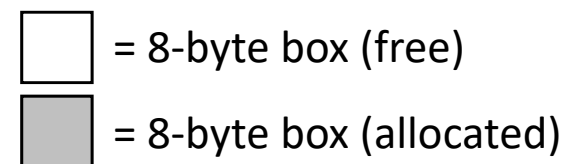

# Implicit Free List Review Questions

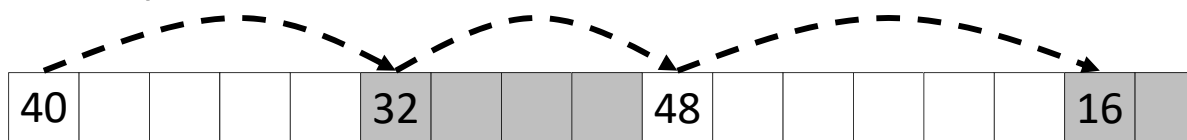

- ❖ What is the block header? What do we store and how?
  - stores info about block*
  - size of block, is-allocated?*
- ❖ What are boundary tags and why do we need them?
  - header and footer (same info)*
  - lowest bit of header*
  - so we can traverse list in either direction (particularly for coalescing)*
- ❖ When we coalesce free blocks, how many neighboring blocks do we need to check on either side? Why is this?
  - just 1 — adjacent free blocks should have already been coalesced*
- ❖ If I want to check the size of the  $n$ -th block forward from the current block, how many memory accesses do I make?
  - $n+1$ : need to read current block's header as well as header of target block to get the size*

# Keeping Track of Free Blocks

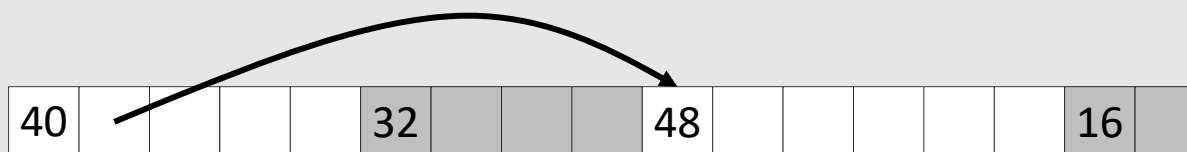

1) *Implicit free list* using length – links all blocks using math

- No actual pointers, and must check each block if allocated or free

2) *Explicit free list* among only the free blocks, using pointers

3) *Segregated free list*

- Different free lists for different size “classes”

4) *Blocks sorted by size*

- Can use a balanced binary tree (e.g. red-black tree) with pointers within each free block, and the length used as a key

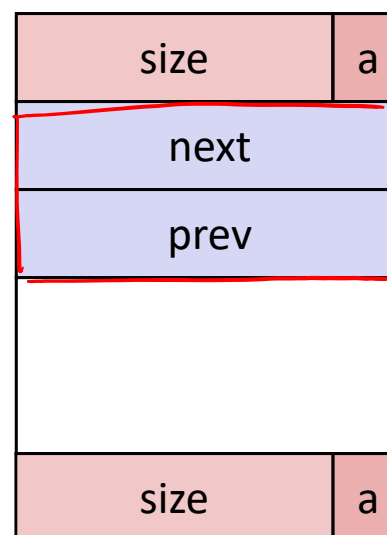

# Explicit Free Lists

Allocated block:

(same as implicit free list)

Free block:

- ❖ Use list(s) of *free* blocks, rather than implicit list of *all* blocks
  - The “next” free block could be anywhere in the heap
    - So we need to store next/previous pointers, not just sizes
  - Since we only track free blocks, so we can use “payload” for pointers
  - Still need boundary tags (header/footer) for coalescing

# Doubly-Linked Lists

## ❖ Linear

- Needs head/root pointer
- First node prev pointer is NULL
- Last node next pointer is NULL
- Good for first-fit, best-fit

## ❖ Circular

- Still have pointer to tell you which node to start with
- No NULL pointers (term condition is back at starting point)
- Good for next-fit, best-fit

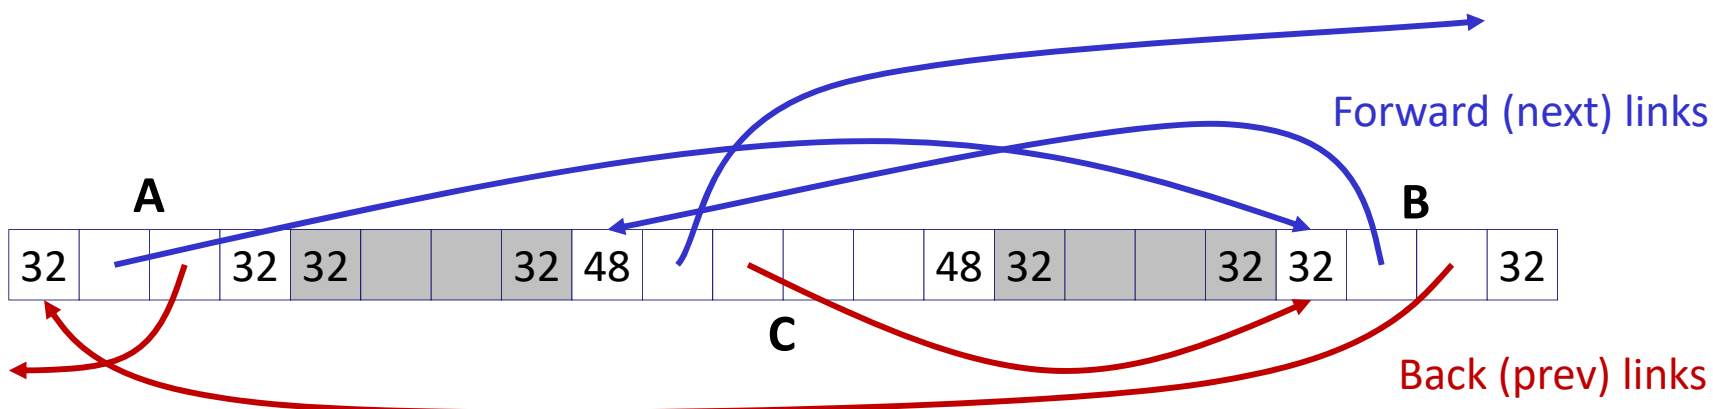

# Explicit Free Lists

- ❖ **Logically:** doubly-linked list

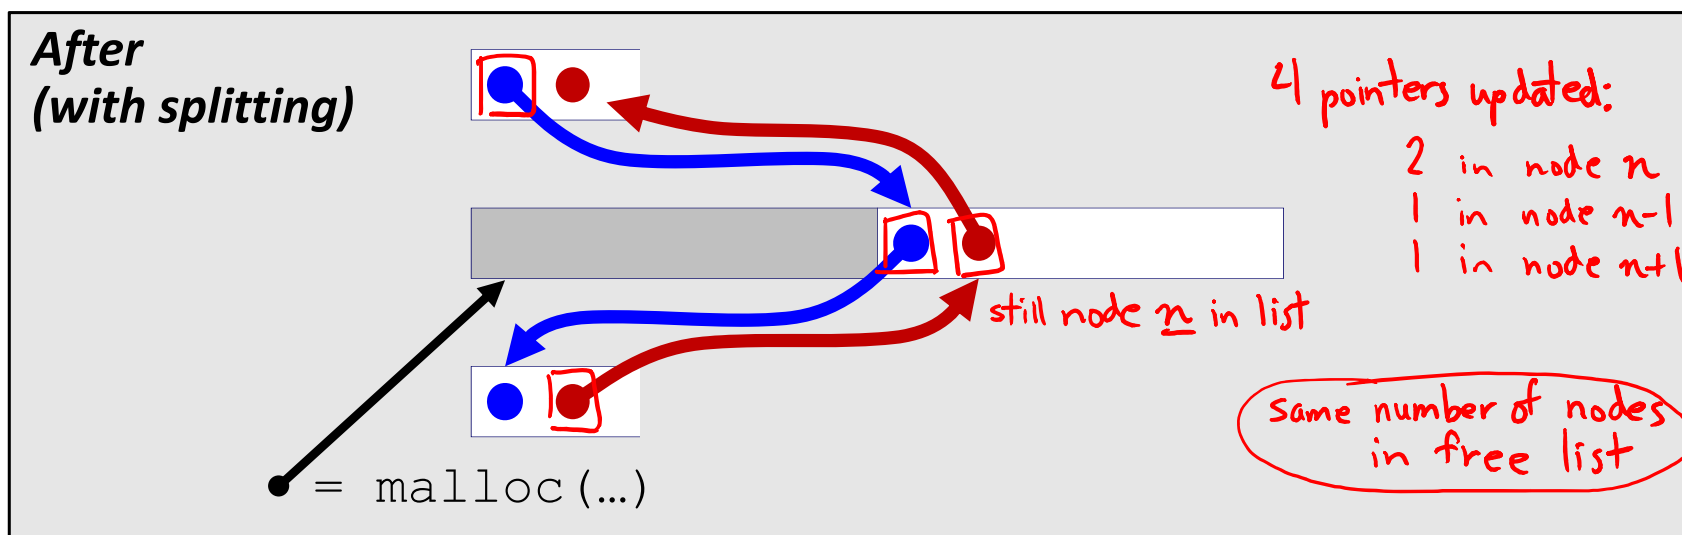

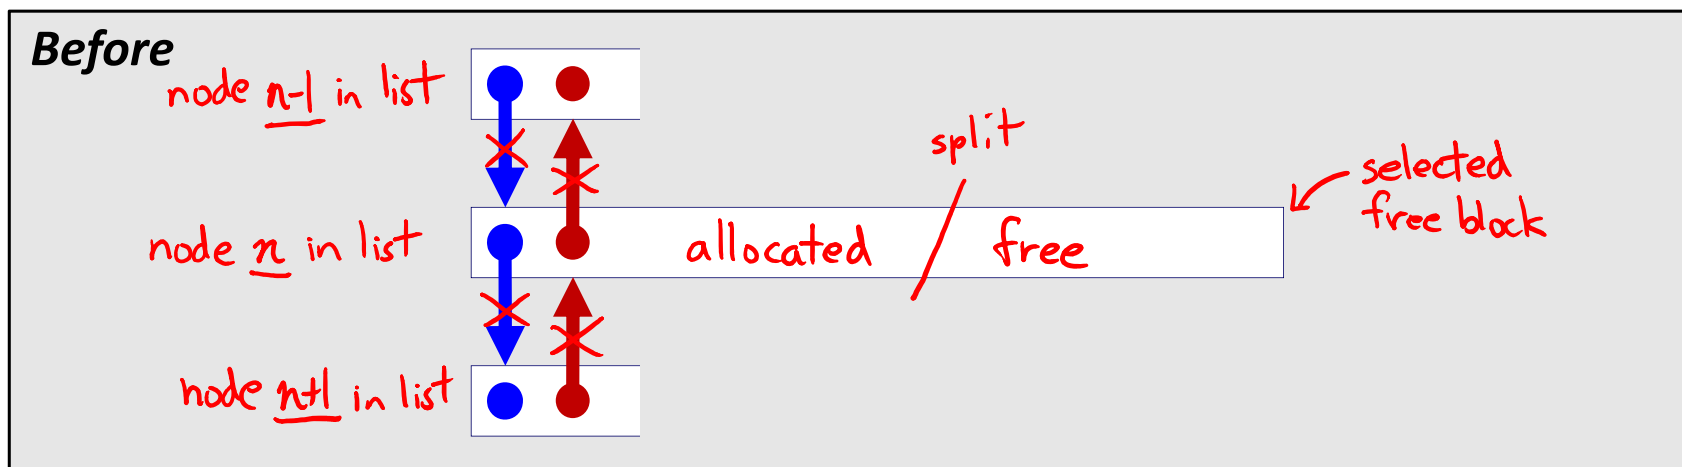

- ❖ **Physically:** blocks can be in any order

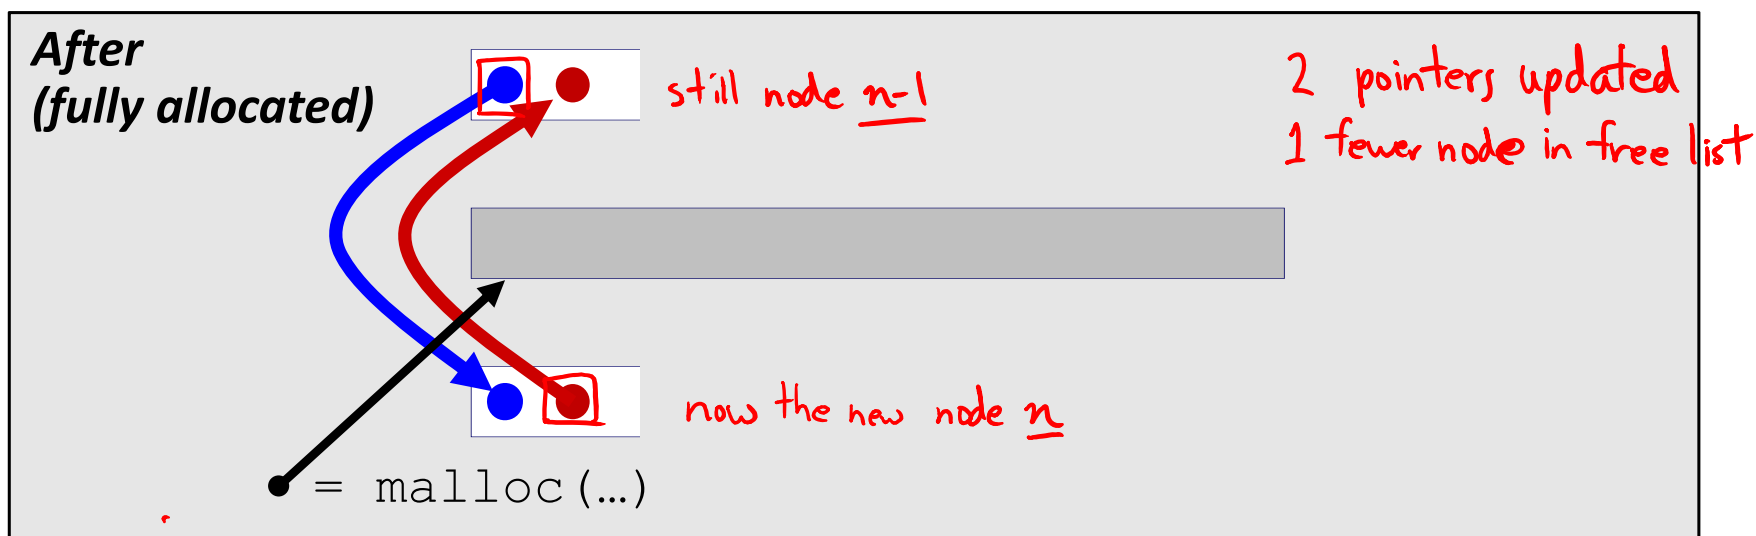

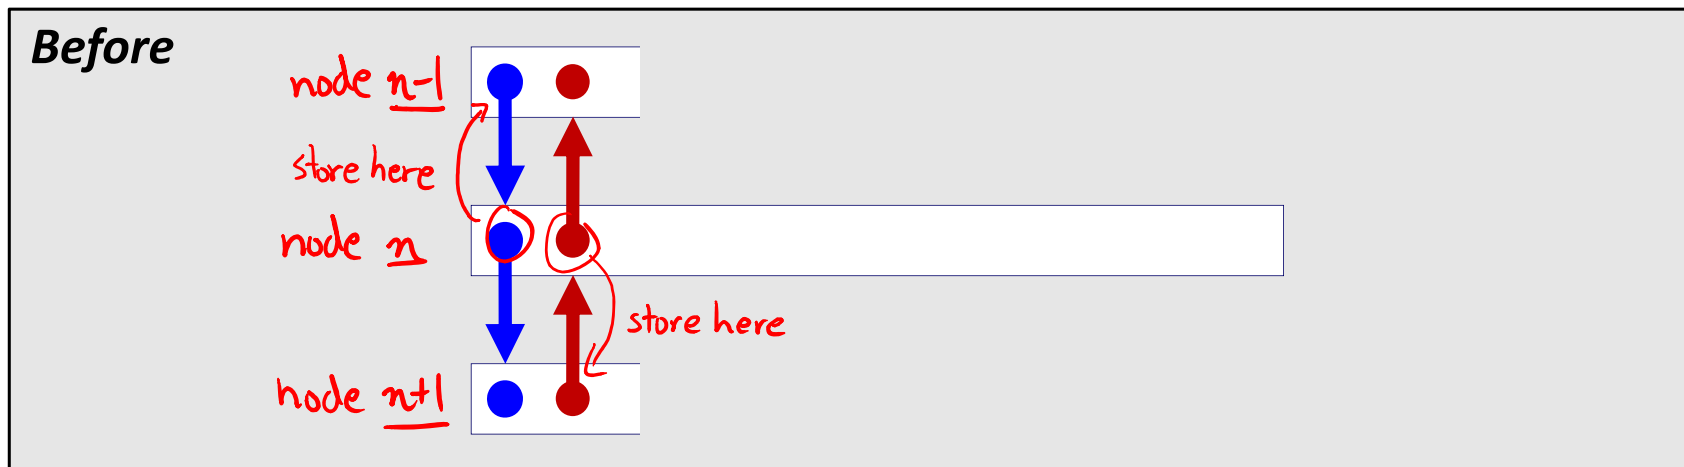

# Allocating From Explicit Free Lists

**Note:** These diagrams are not very specific about where inside a block a pointer points. In reality we would always point to one place (e.g. start/header of a block).

# Allocating From Explicit Free Lists

**Note:** These diagrams are not very specific about where inside a block a pointer points. In reality we would always point to one place (e.g. start/header of a block).

# Freeing With Explicit Free Lists

- ❖ *Insertion policy*: Where in the free list do you put the newly freed block?

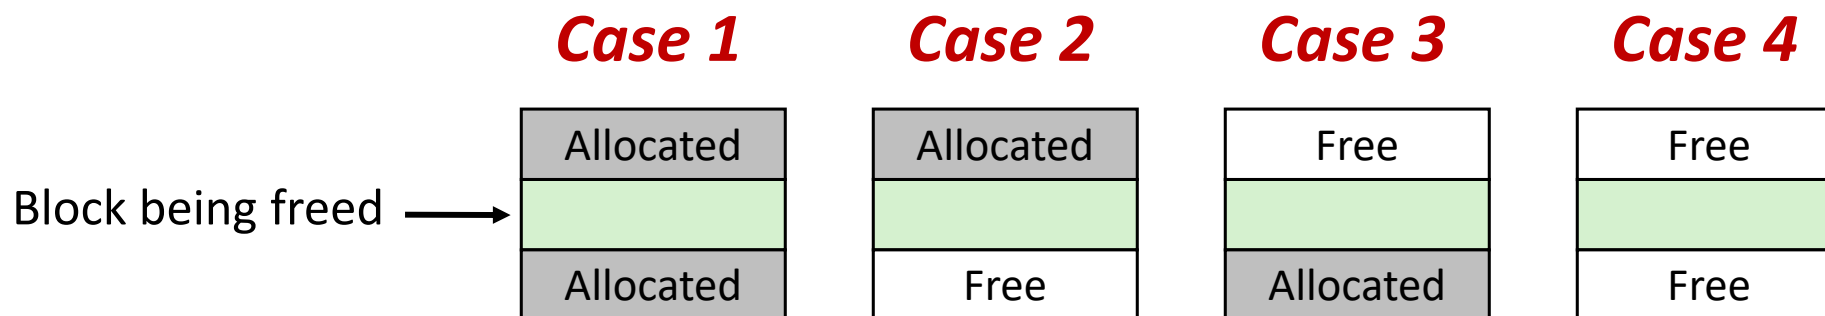

## ★ LIFO (last-in-first-out) policy

- Insert freed block at the beginning (head) of the free list
- Pro: simple and constant time
- Con: studies suggest fragmentation is worse than the alternative

## ■ Address-ordered policy

- Insert freed blocks so that free list blocks are always in address order:  
 $address(previous) < address(current) < address(next)$
- Con: requires linear-time search
- Pro: studies suggest fragmentation is better than the alternative

# Coalescing in Explicit Free Lists

❖ Neighboring free blocks are *already part of the free list*

- 1) Remove old block from free list
- 2) Create new, larger coalesced block
- 3) Add new block to free list (insertion policy)

❖ How do we tell if a neighboring block is free?

can still use boundary tags (don't need to search free list). other implementations possible (see Lab 5)

# Freeing with LIFO Policy (Case 1)

Boundary tags not shown, but don't forget about them!

❖ Insert the freed block at the root of the list

# Freeing with LIFO Policy (Case 2)

Boundary tags not shown, but don't forget about them!

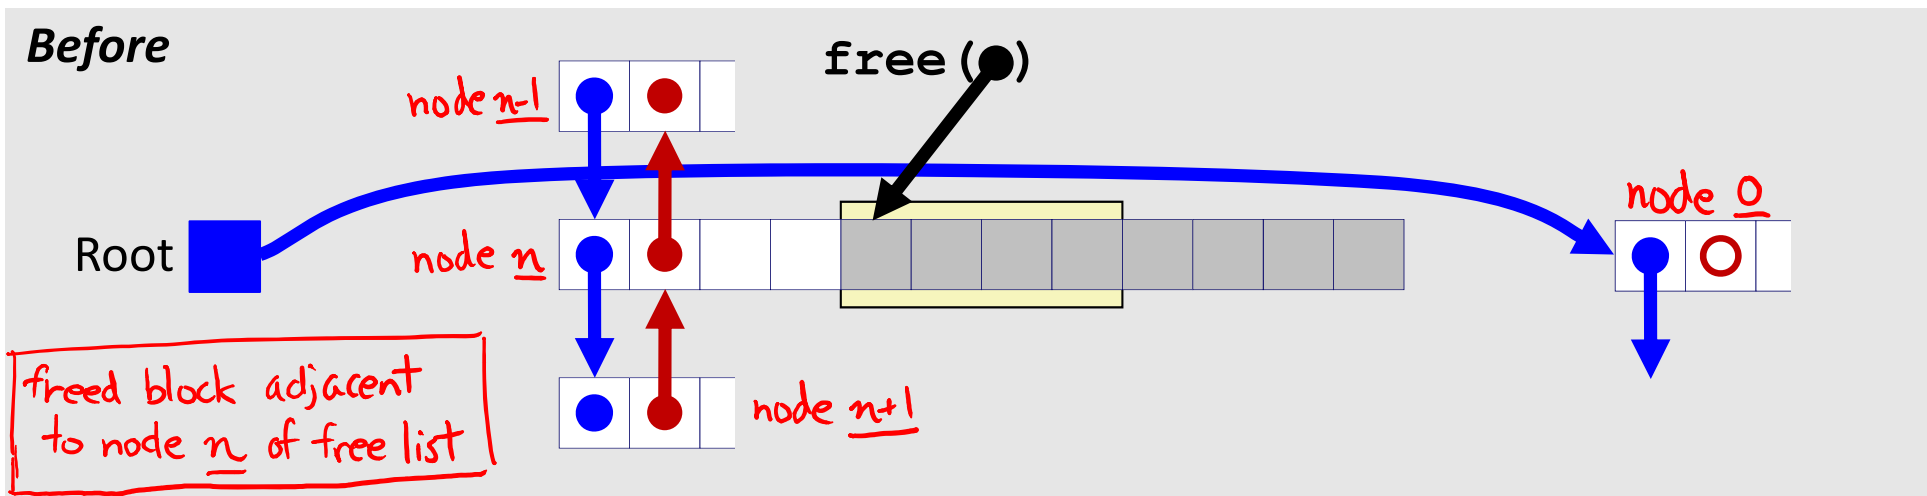

- ❖ Splice successor block out of list, coalesce both memory blocks, and insert the new block at the root of the list

# Freeing with LIFO Policy (Case 3)

Boundary tags not shown, but don't forget about them!

- ❖ Splice predecessor block out of list, coalesce both memory blocks, and insert the new block at the root of the list

# Freeing with LIFO Policy (Case 4)

Boundary tags not shown, but don't forget about them!

❖ Splice predecessor and successor blocks out of list, coalesce all 3 memory blocks, and insert the new block at the root of the list

# Do we always need the boundary tags?

Allocated block:

(same as implicit free list)

Free block:

❖ Lab 5 suggests no...

# Explicit List Summary

- ❖ Comparison with implicit list:
  - Block allocation is linear time in number of *free* blocks instead of *all* blocks
    - *Much faster* when most of the memory is full
  - Slightly more complicated allocate and free since we need to splice blocks in and out of the list
  - Some extra space for the links (2 extra pointers needed for each free block)
    - Increases minimum block size, leading to more internal fragmentation
- ❖ Most common use of explicit lists is in conjunction with *segregated free lists*
  - Keep multiple linked lists of different size classes, or possibly for different types of objects

# BONUS SLIDES

The following slides are about the **SegList Allocator**, for those curious. You will NOT be expected to know this material.

# SegList Allocator

- ❖ Have an array of free lists for various size classes
- ❖ To allocate a block of size  $n$ :
  - Search appropriate free list for block of size  $m \geq n$
  - If an appropriate block is found:
    - [Optional] Split block and place free fragment on appropriate list
  - If no block is found, try the next larger class
    - Repeat until block is found
- ❖ If no block is found:
  - Request additional heap memory from OS (using `sbrk`)
  - Place remainder of additional heap memory as a single free block in appropriate size class

# SegList Allocator

- ❖ Have an array of free lists for various size classes
- ❖ To free a block:
  - Mark block as free
  - Coalesce (if needed)
  - Place on appropriate class list

# SegList Advantages

- ❖ Higher throughput
  - Search is log time for power-of-two size classes
- ❖ Better memory utilization
  - First-fit search of seglist approximates a best-fit search of entire heap
  - *Extreme case*: Giving every block its own size class is no worse than best-fit search of an explicit list
  - Don't need to use space for block size for the fixed-size classes
