Administrivia

- ❖ hw7 due Monday, hw8 due Wednesday
- ❖ Lab 1b due Monday (10/14) at 11:59 pm
 - You have *late day tokens* available

Roadmap

C:

```
car *c = malloc(sizeof(car));
c->miles = 100;
c->gals = 17;
float mpg = get_mpg(c);
free(c);
```

Java:

```
Car c = new Car();
c.setMiles(100);
c.setGals(17);
float mpg =
    c.getMPG();
```

- Memory & data
- Integers & floats
- x86 assembly**
- Procedures & stacks
- Executables
- Arrays & structs
- Memory & caches
- Processes
- Virtual memory
- Memory allocation
- Java vs. C

Assembly language:

```
get_mpg:
    pushq    %rbp
    movq    %rsp, %rbp
    ...
    popq    %rbp
    ret
```

Machine code:

```
0111010000011000
100011010000010000000010
1000100111000010
110000011111101000011111
```

Computer system:

OS:

Architecture Sits at the Hardware Interface

Source code

Different applications or algorithms

Compiler

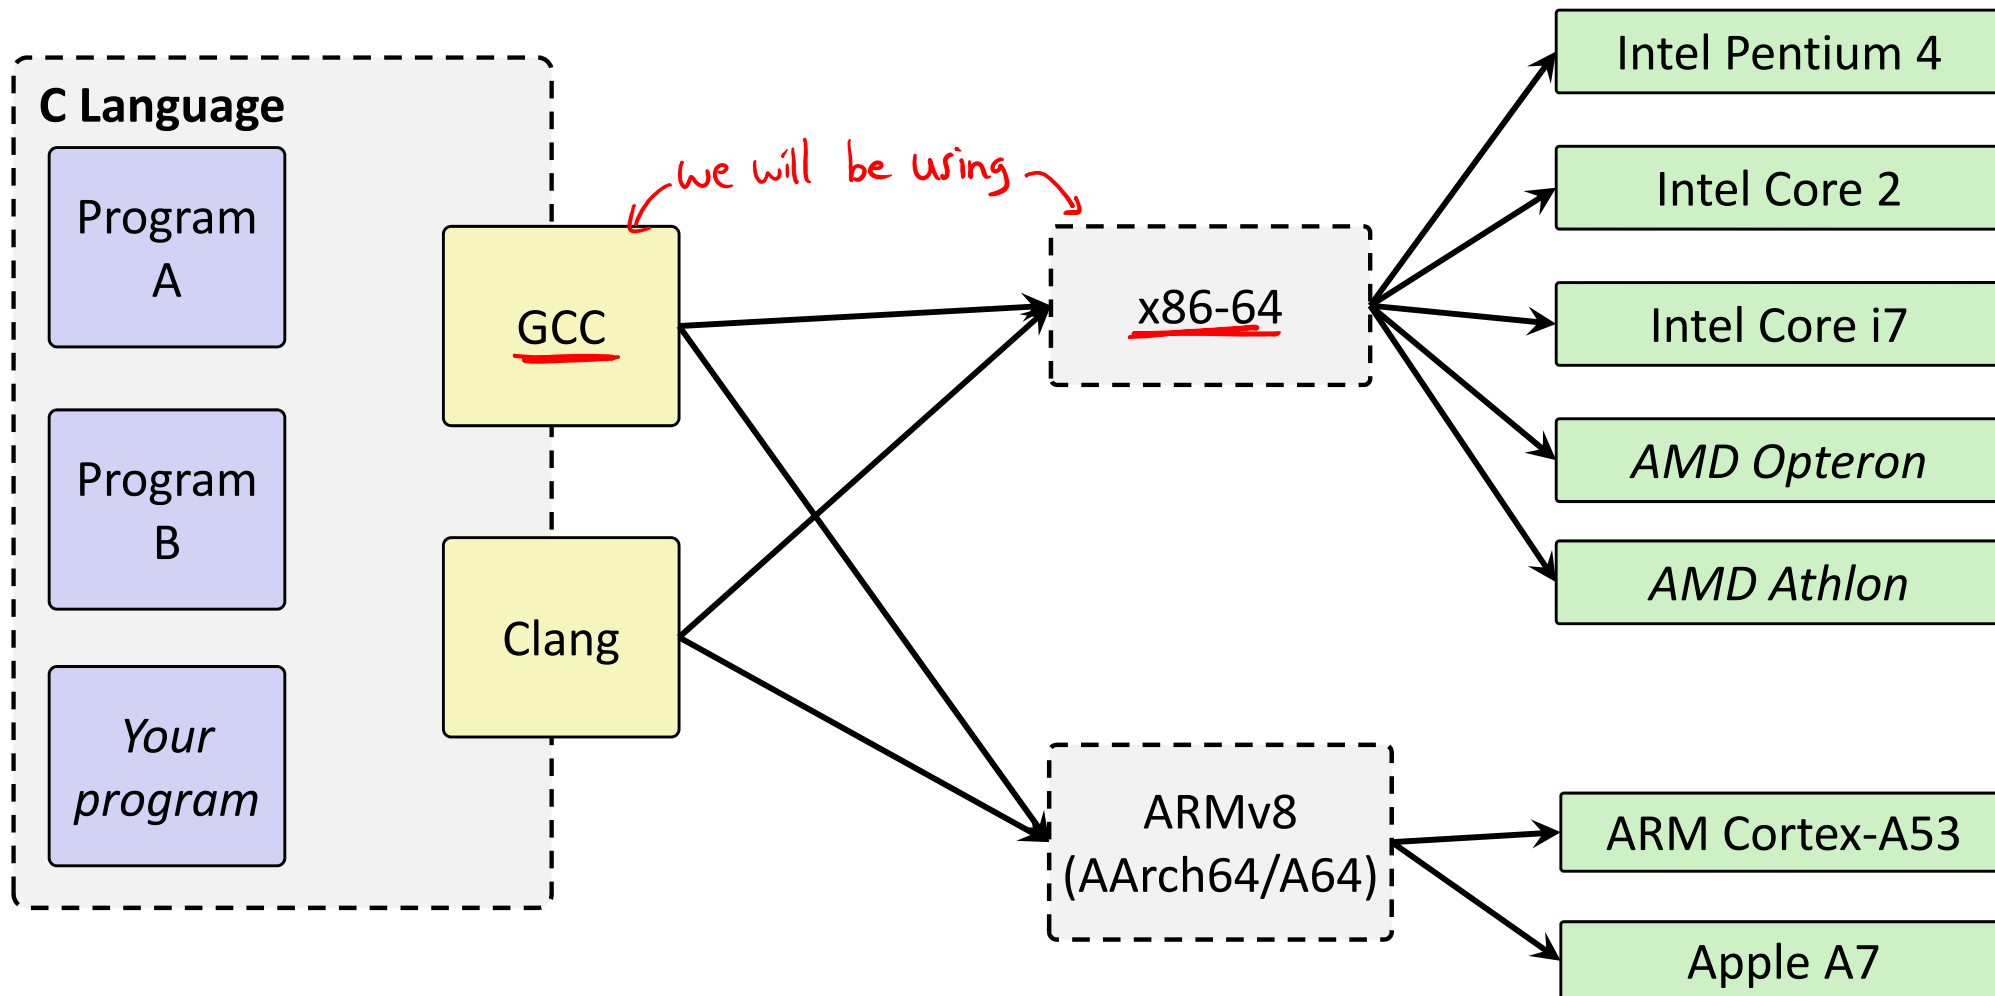

Perform optimizations, generate instructions

Architecture

Instruction set

Hardware

Different implementations

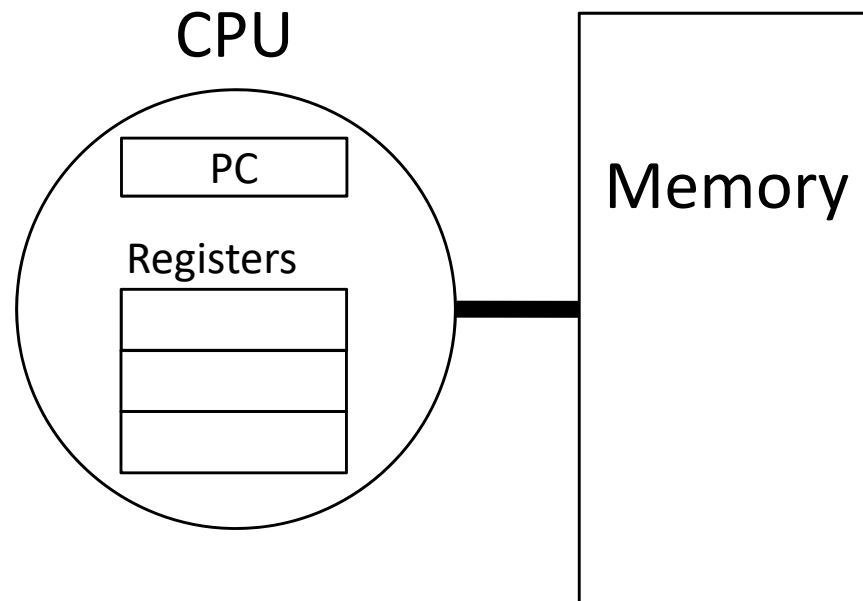

Definitions

- ❖ **Architecture (ISA):** The parts of a processor design that one needs to understand to write assembly code
 - “What is directly visible to software”
- ❖ **Microarchitecture:** Implementation of the architecture
 - CSE/EE 469

Instruction Set Architectures

- ❖ The ISA defines:
 - The system's **state** (e.g. registers, memory, program counter)
 - The **instructions** the CPU can execute
 - The **effect** that each of these instructions will have on the system state

Instruction Set Philosophies

- ❖ *Complex Instruction Set Computing (CISC)*: Add more and more elaborate and specialized instructions as needed
 - Lots of tools for programmers to use, but hardware must be able to handle all instructions
 - x86-64 is CISC, but only a small subset of instructions encountered with Linux programs
- ❖ *Reduced Instruction Set Computing (RISC)*: Keep instruction set small and regular
 - Easier to build fast hardware
 - Let software do the complicated operations by composing simpler ones

General ISA Design Decisions

- ❖ Instructions
 - What instructions are available? What do they do?
 - How are they encoded?

- ❖ Registers
 - How many registers are there?
 - How wide are they?

- ❖ Memory
 - How do you specify a memory location?

Mainstream ISAs

x86

Designer	Intel, AMD
Bits	16-bit, 32-bit and 64-bit
Introduced	1978 (16-bit), 1985 (32-bit), 2003 (64-bit)
Design	CISC
Type	Register-memory
Encoding	Variable (1 to 15 bytes)
Endianness	Little

Macbooks & PCs
(Core i3, i5, i7, M)
[x86-64 Instruction Set](#)

ARM architectures

Designer	ARM Holdings
Bits	32-bit, 64-bit
Introduced	1985; 31 years ago
Design	RISC
Type	Register-Register
Encoding	AArch64/A64 and AArch32/A32 use 32-bit instructions, T32 (Thumb-2) uses mixed 16- and 32-bit instructions. ARMv7 user-space compatibility ^[1]
Endianness	Bi (little as default)

Smartphone-like devices
(iPhone, iPad, Raspberry Pi)
[ARM Instruction Set](#)

MIPS

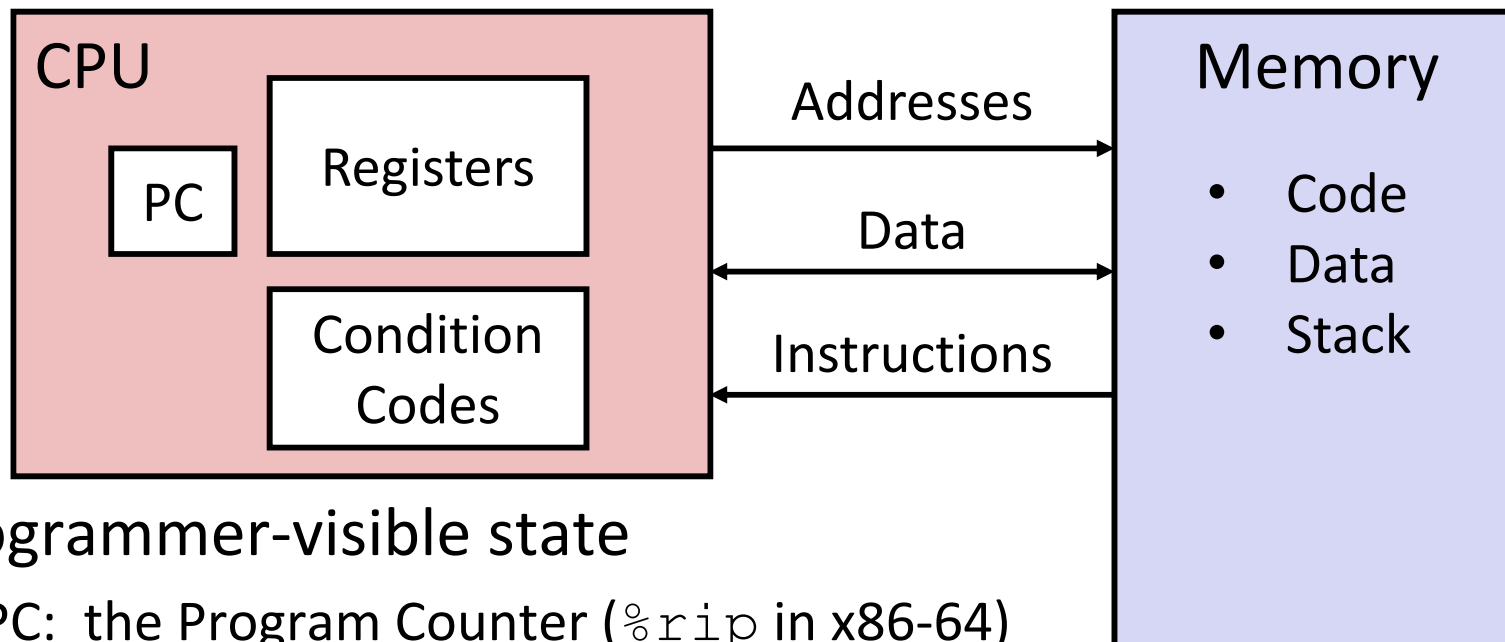

Designer	MIPS Technologies, Inc.
Bits	64-bit (32→64)
Introduced	1981; 35 years ago
Design	RISC
Type	Register-Register
Encoding	Fixed
Endianness	Bi

Digital home & networking equipment
(Blu-ray, PlayStation 2)
[MIPS Instruction Set](#)

Writing Assembly Code? In 2019???

- ❖ Chances are, you'll never write a program in assembly, but understanding assembly is the key to the machine-level execution model:
 - Behavior of programs in the presence of bugs
 - When high-level language model breaks down
 - Tuning program performance
 - Understand optimizations done/not done by the compiler
 - Understanding sources of program inefficiency
 - Implementing systems software
 - What are the “states” of processes that the OS must manage
 - Using special units (timers, I/O co-processors, etc.) inside processor!
 - Fighting malicious software
 - Distributed software is in binary form

Assembly Programmer's View

❖ Programmer-visible state

- PC: the Program Counter (`%rip` in x86-64)
 - Address of next instruction
- Named registers
 - Together in “register file”
 - Heavily used program data
- Condition codes
 - Store status information about most recent arithmetic operation
 - Used for conditional branching

❖ Memory

- Byte-addressable array
- Code and user data
- Includes *the Stack* (for supporting procedures)

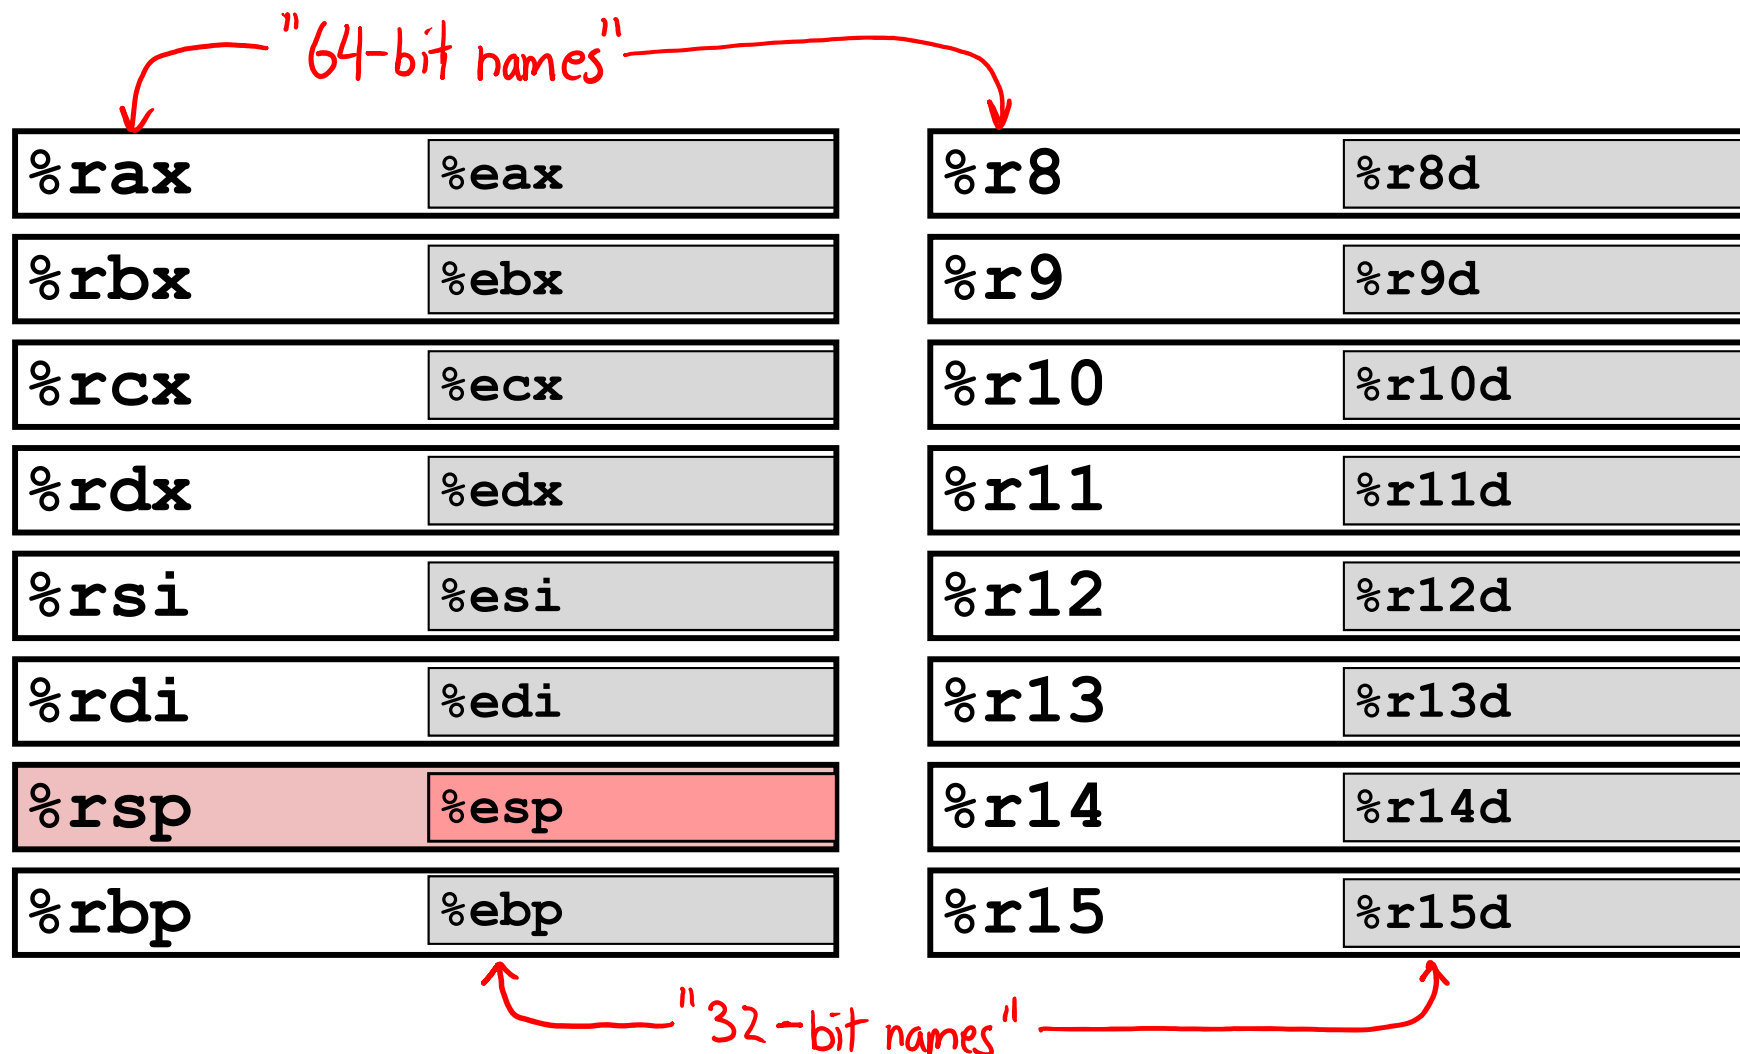

x86-64 Assembly “Data Types”

- ✧ Integral data of 1, 2, 4, or 8 bytes
 - Data values
 - Addresses
 - ❖ Floating point data of 4, 8, 10 or 2x8 or 4x4 or 8x2
 - Different registers for those (*e.g.* `%xmm1`, `%ymm2`)
 - Come from *extensions to x86* (SSE, AVX, ...)
 - ❖ No aggregate types such as arrays or structures
 - Just contiguously allocated bytes in memory
 - ❖ Two common syntaxes
 - ✓ ■ “AT&T”: used by our course, slides, textbook, gnu tools, ...
 - ✗ ■ “Intel”: used by Intel documentation, Intel tools, ...
 - Must know which you’re reading
- } Not covered
In 351

What is a Register?

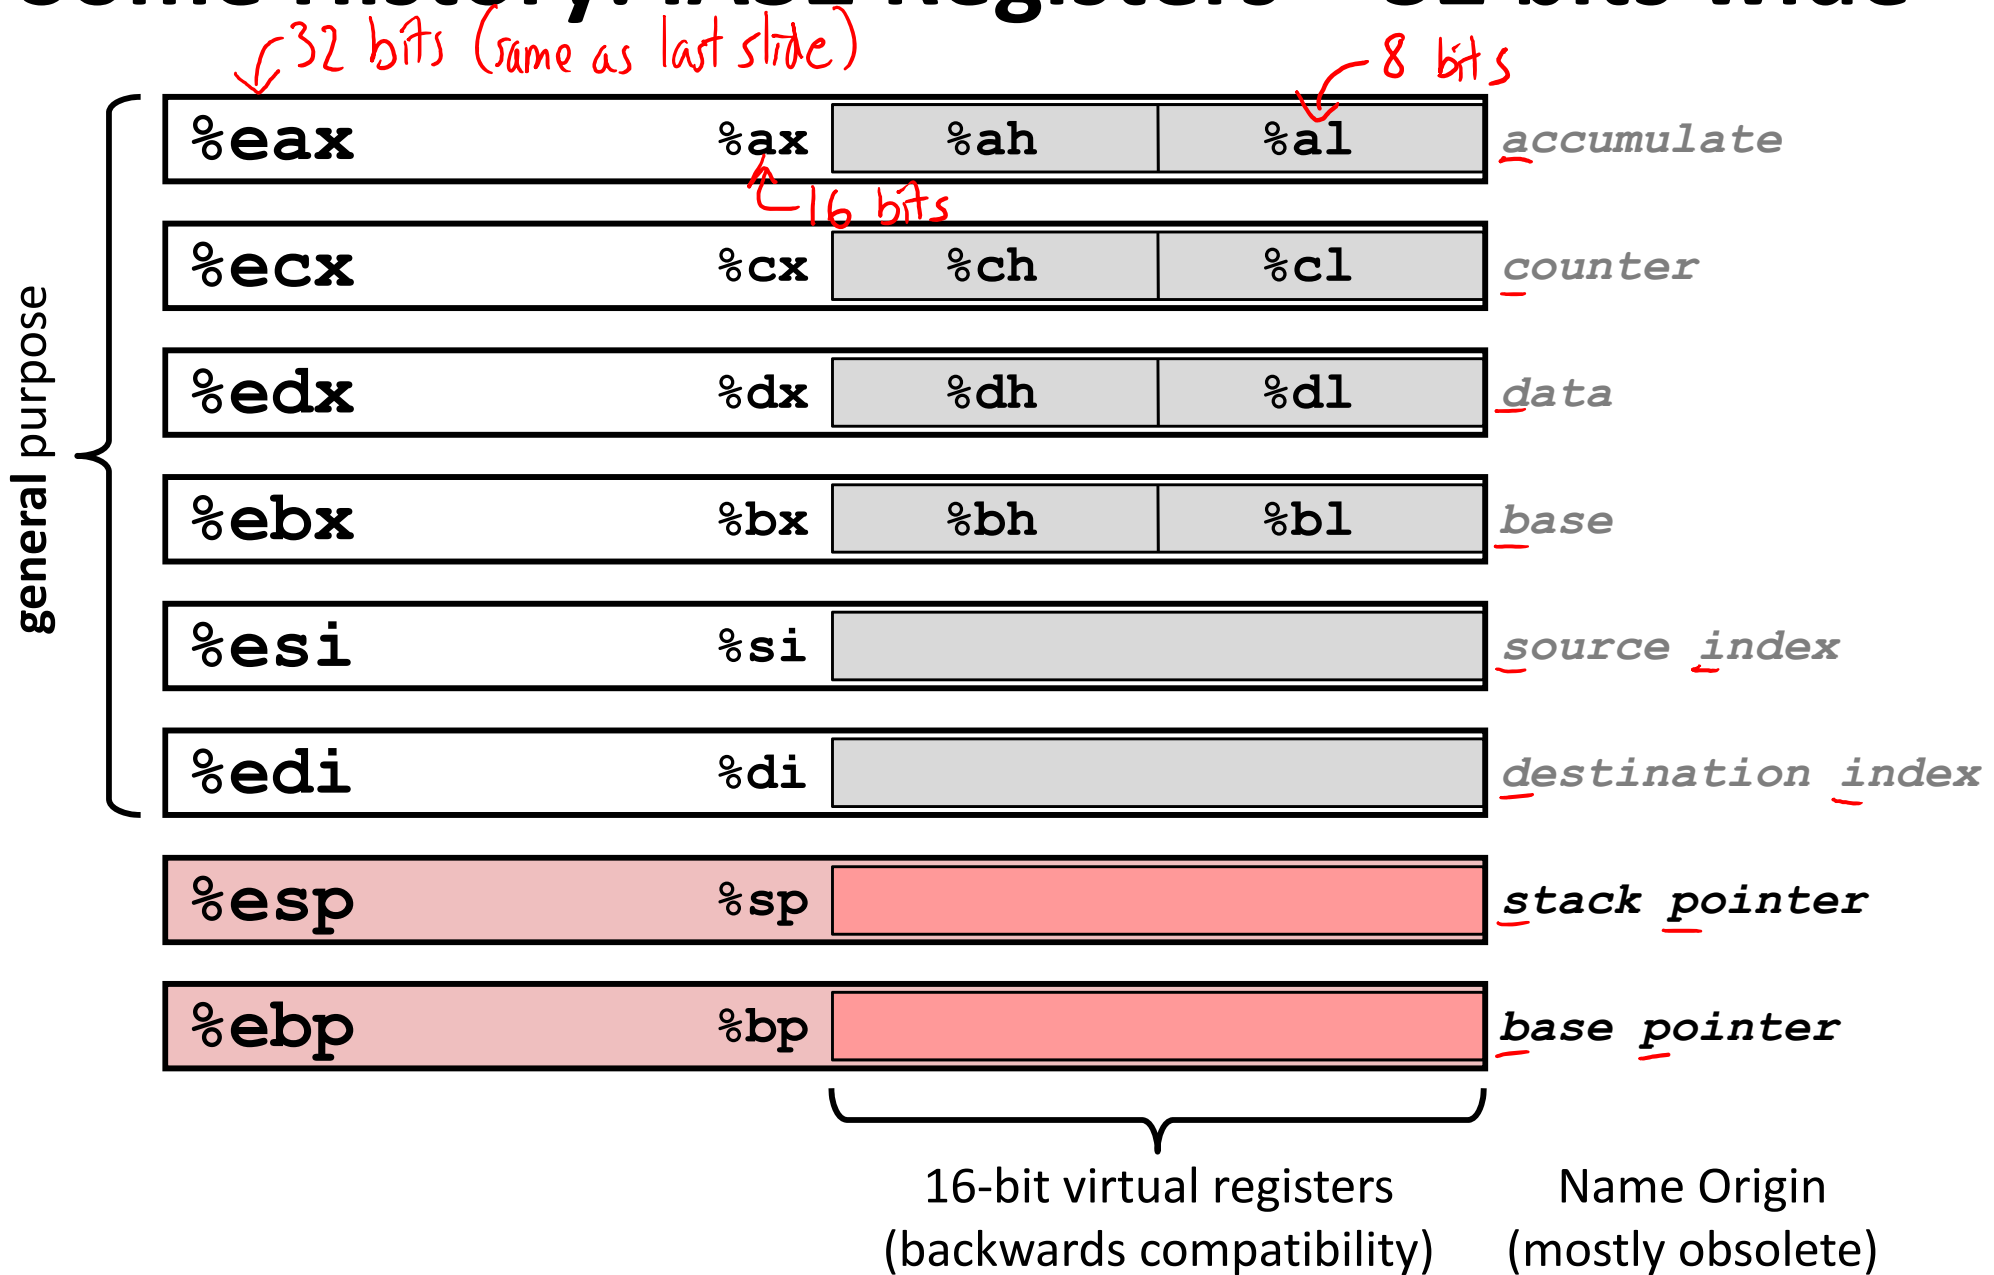

- ❖ A location in the CPU that stores a small amount of data, which can be accessed very quickly (once every clock cycle)
- ❖ Registers have *names*, not *addresses*
 - In assembly, they start with % (e.g. %rsi)
- ❖ Registers are at the heart of assembly programming
 - They are a precious commodity in all architectures, but *especially x86 only 16 of them...*

x86-64 Integer Registers – 64 bits wide

- Can reference low-order 4 bytes (also low-order 2 & 1 bytes)

Some History: IA32 Registers – 32 bits wide

Memory

- ❖ Addresses
 - `0x7FFFD024C3DC`
- ❖ Big
 - `~ 8 GiB`
- ❖ Slow
 - ~50-100 ns 
- ❖ Dynamic
 - Can “grow” as needed while program runs

vs. Registers

- vs. Names
 - `%rdi`
- vs. Small
 - `(16 x 8 B) = 128 B`
- vs. Fast
 - sub-nanosecond timescale
- vs. Static
 - fixed number in hardware

Three Basic Kinds of Instructions

1) Transfer data between memory and register

- *Load* data from memory into register
 - `%reg = Mem[address]`
- *Store* register data into memory
 - `Mem[address] = %reg`

Remember: Memory is indexed just like an array of bytes!

2) Perform arithmetic operation on register or memory data

- `c = a + b;` `z = x << y;` `i = h & g;`

3) Control flow: what instruction to execute next

- Unconditional jumps to/from procedures
- Conditional branches

Operand types

❖ **Immediate:** Constant integer data

- Examples: \$0x400, \$-533
hex decimal
- Like C literal, but prefixed with '\$'
- Encoded with 1, 2, 4, or 8 bytes
depending on the instruction

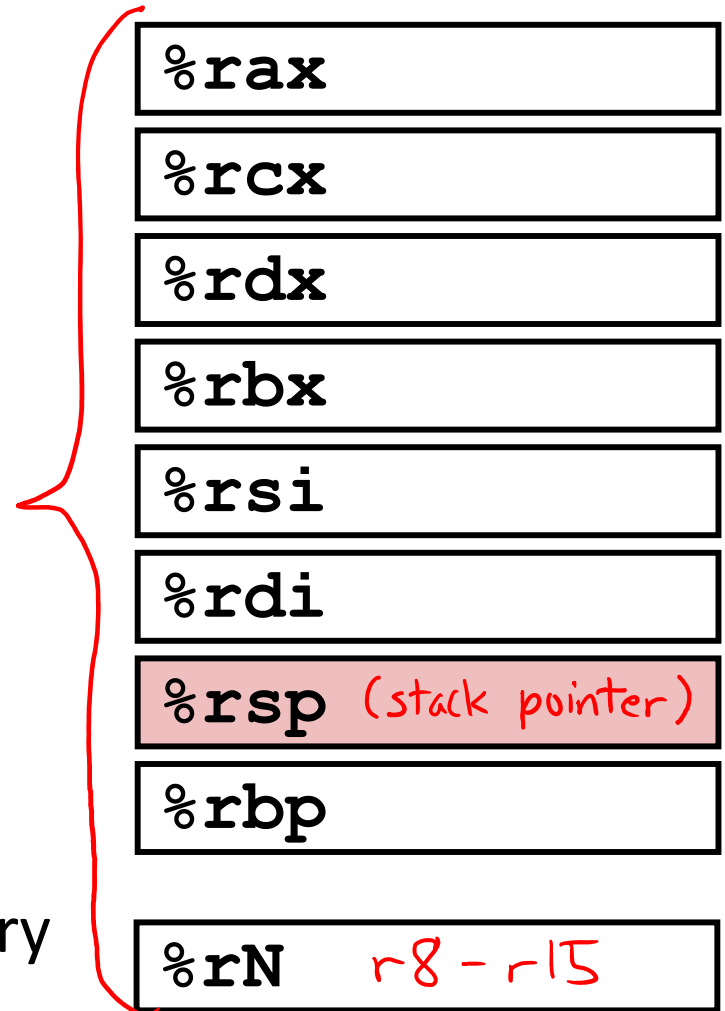

❖ **Register:** 1 of 16 integer registers

- Examples: %rax, %r13
- But %rsp reserved for special use
- Others have special uses for particular instructions

❖ **Memory:** Consecutive bytes of memory at a computed address

- Simplest example: (%rax)
- Various other "address modes"

← take data in %rax, treat as address, pull data at that address

x86-64 Introduction

- ❖ Data transfer instruction (`mov`)
- ❖ Arithmetic operations
- ❖ Memory addressing modes
 - `swap` example
- ❖ Address computation instruction (`lea`)

Moving Data

- ❖ General form: `mov_ source, destination`
- instruction name* → `mov`
width specifier → `_`
copies data → `source, destination`
- Missing letter (`_`) specifies size of operands
 - Note that due to backwards-compatible support for 8086 programs (16-bit machines!), “word” means 16 bits = 2 bytes in x86 instruction names
 - Lots of these in typical code

❖ `movb src, dst`

- Move 1-byte “byte”

❖ `movw src, dst`

- Move 2-byte “word”

❖ `movl src, dst`

- Move 4-byte “long word”

❖ `movq src, dst`

- Move 8-byte “quad word”

Operand Combinations

x86 C
 Imm ↔ Constant
 Reg ↔ Variable
 Mem ↔ dereferencing
C Analog a pointer

	Source	Dest	Src, Dest	
movq	Imm	Reg	movq \$0x4, %rax	var_a = 0x4;
		Mem	movq \$-147, (%rax)	*p_a = -147;
	Reg	Reg	movq %rax, %rdx	var_d = var_a;
		Mem	movq %rax, (%rdx)	*p_d = var_a;
	Mem	Reg	movq (%rax), %rdx	var_d = *p_a;

❖ *Cannot do memory-memory transfer with a single instruction*

■ How would you do it?

① Mem → Reg

```
movq (%rax), %rdx
```

② Reg → Mem

```
movq %rdx, (%rbx)
```

Some Arithmetic Operations

other ways to set to 0:
 subq %rcx, %rcx
 andq \$0, %rcx
 xorq %rcx, %rcx
 imulq \$0, %rcx

❖ Binary (two-operand) Instructions:

Maximum of one memory operand

- Beware argument order!
- No distinction between signed and unsigned
 - Only arithmetic vs. logical shifts
- How do you implement

Format	Computation
<code>addq src, dst</code>	<code>dst = dst + src</code>
<code>subq src, dst</code>	<code>dst = dst - src</code>
<code>imulq src, dst</code>	<code>dst = dst * src</code>
<code>sarq src, dst</code>	<code>dst = dst >> src</code>
<code>shrq src, dst</code>	<code>dst = dst >> src</code>
<code>shlq src, dst</code>	<code>dst = dst << src</code>
<code>xorq src, dst</code>	<code>dst = dst ^ src</code>
<code>andq src, dst</code>	<code>dst = dst & src</code>
<code>orq src, dst</code>	<code>dst = dst src</code>

Imm, Reg, or Mem

(dst += src)
 signed mult
 Arithmetic
 Logical
 (same as salq)

"r3 = r1 + r2"?
 %rcx %rax %rbx

operation operand size specifier (b, w, l, q)

① clear r3 `movq $0, %rcx`
 ② add r1 to r3 `addq %rax, %rcx`
 ③ add r2 to r3 `addq %rbx, %rcx`

`movq %rax, %rcx`
`addq %rbx, %rcx`

Some Arithmetic Operations

❖ Unary (one-operand) Instructions:

Format	Computation	
incq <i>dst</i>	$dst = dst + 1$	increment
decq <i>dst</i>	$dst = dst - 1$	decrement
negq <i>dst</i>	$dst = -dst$	negate
notq <i>dst</i>	$dst = \sim dst$	bitwise complement

❖ See CSPP Section 3.5.5 for more instructions: `mulq`, `cqto`, `idivq`, `divq`

Arithmetic Example

Register	Use(s)
<u>%rdi</u>	1 st argument (x)
<u>%rsi</u>	2 nd argument (y)
<u>%rax</u>	return value

Convention!

```

long simple_arith(long x, long y)
{
    long t1 = x + y;
    long t2 = t1 * 3;
    return t2;
}
    
```

don't actually need new variables!

```

y += x;
y *= 3;
long r = y;
return r;
    
```

must return in %rax

```

simple_arith:
    addq    %rdi, %rsi
    imulq   $3,  %rsi
    movq    %rsi, %rax
    ret
    
```

return

Example of Basic Addressing Modes

```
void swap(long *xp, long *yp)
{
    long t0 = *xp;
    long t1 = *yp;
    *xp = t1;
    *yp = t0;
}
```

swap: *src* , *dst* (AT &T syntax)

```
    movq    (%rdi), %rax
    movq    (%rsi), %rdx
    movq    %rdx, (%rdi)
    movq    %rax, (%rsi)
    ret
```

Mem operands

Understanding swap ()

```
void swap(long *xp, long *yp)
{
    long t0 = *xp;
    long t1 = *yp;
    *xp = t1;
    *yp = t0;
}
```

```
swap:
    movq    (%rdi), %rax
    movq    (%rsi), %rdx
    movq    %rdx, (%rdi)
    movq    %rax, (%rsi)
    ret
```

<u>Register</u>		<u>Variable</u>
%rdi	↔	xp
%rsi	↔	yp
%rax	↔	t0
%rdx	↔	t1

Understanding swap ()

```

swap:
    movq    (%rdi), %rax    # t0 = *xp
    movq    (%rsi), %rdx    # t1 = *yp
    movq    %rdx, (%rdi)    # *xp = t1
    movq    %rax, (%rsi)    # *yp = t0
    ret
    
```

src dst

Comment

Understanding swap ()

```
swap:
```

```
movq    (%rdi), %rax    # t0 = *xp  
movq    (%rsi), %rdx    # t1 = *yp  
movq    %rdx, (%rdi)    # *xp = t1  
movq    %rax, (%rsi)    # *yp = t0  
ret
```

Understanding swap ()

```

swap:
    movq    (%rdi), %rax    # t0 = *xp
    movq    (%rsi), %rdx    # t1 = *yp
    movq    %rdx, (%rdi)    # *xp = t1
    movq    %rax, (%rsi)    # *yp = t0
    ret
    
```

Understanding swap ()

```

swap:
    movq    (%rdi), %rax    # t0 = *xp
    movq    (%rsi), %rdx    # t1 = *yp
    movq    %rdx, (%rdi)   # *xp = t1
    movq    %rax, (%rsi)   # *yp = t0
    ret
    
```

Understanding swap ()

```

swap:
    movq    (%rdi), %rax    # t0 = *xp
    movq    (%rsi), %rdx    # t1 = *yp
    movq    %rdx, (%rdi)    # *xp = t1
    movq    %rax, (%rsi)    # *yp = t0
    ret
    
```

Memory Addressing Modes: Basic

- ❖ **Indirect:** (R) $\text{Mem}[\text{Reg}[R]]$
 - Data in register R specifies the memory address
 - Like pointer dereference in C
 - Example: `movq (%rcx), %rax`
- Handwritten notes:*
 - "name of register" with an arrow pointing to (R)
 - "treat Mem as an array" with an arrow pointing to $\text{Mem}[\text{Reg}[R]]$
 - "value stored in register" with an arrow pointing to $\text{Reg}[R]$

- ❖ **Displacement:** $D (R)$ $\text{Mem}[\text{Reg}[R]+D]$
 - Data in register R specifies the *start* of some memory region
 - Constant displacement D specifies the offset from that address
 - Example: `movq 8(%rbp), %rdx`
- Handwritten notes:*
 - "no space" with an arrow pointing to the space between D and (R) in the displacement mode notation.

Complete Memory Addressing Modes

❖ General:

$$ar[i] \leftrightarrow *(ar + i) \rightarrow \text{Mem}[ar + i * \text{size of (data type)}]$$

$$\blacksquare D(Rb, Ri, S) \quad \text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri] * S + D]$$

- Rb: Base register (any register)
- Ri: Index register (any register except %rsp)
- S: Scale factor (1, 2, 4, 8) – *why these numbers?* data type widths
- D: Constant displacement value (a.k.a. immediate)

❖ Special cases (see CSPP Figure 3.3 on p.181)

$$\blacksquare D(Rb, Ri) \quad \text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri] + D] \quad (S=1)$$

$$\blacksquare (Rb, Ri, S) \quad \text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri] * S] \quad (D=0)$$

$$\blacksquare (Rb, Ri) \quad \text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri]] \quad (S=1, D=0)$$

$$\blacksquare (, Ri, S) \quad \text{Mem}[\text{Reg}[Ri] * S] \quad (Rb=0, D=0)$$

↑ so reg name not interpreted as Rb

Address Computation Examples

<code>%rdx</code>	<code>0xf000</code>
<code>%rcx</code>	<code>0x0100</code>

$$D(Rb, Ri, S) \rightarrow \text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri] * S + D]$$

↑ ignore the memory access for now

Expression	Address Computation	Address <i>(8 bytes wide)</i>
<code>0x8(%rdx)</code>		
<code>(%rdx,%rcx)</code>		
<code>(%rdx,%rcx,4)</code>		
<code>0x80(,%rdx,2)</code>		

Summary

- ❖ x86-64 is a complex instruction set computing (CISC) architecture
 - There are 3 types of operands in x86-64
 - Immediate, Register, Memory
 - There are 3 types of instructions in x86-64
 - Data transfer, Arithmetic, Control Flow
- ❖ **Memory Addressing Modes:** The addresses used for accessing memory in `mov` (and other) instructions can be computed in several different ways
 - *Base register, index register, scale factor, and displacement* map well to pointer arithmetic operations
