Caches II

CSE 351 Autumn 2019

Instructor:

Justin Hsia

Teaching Assistants:

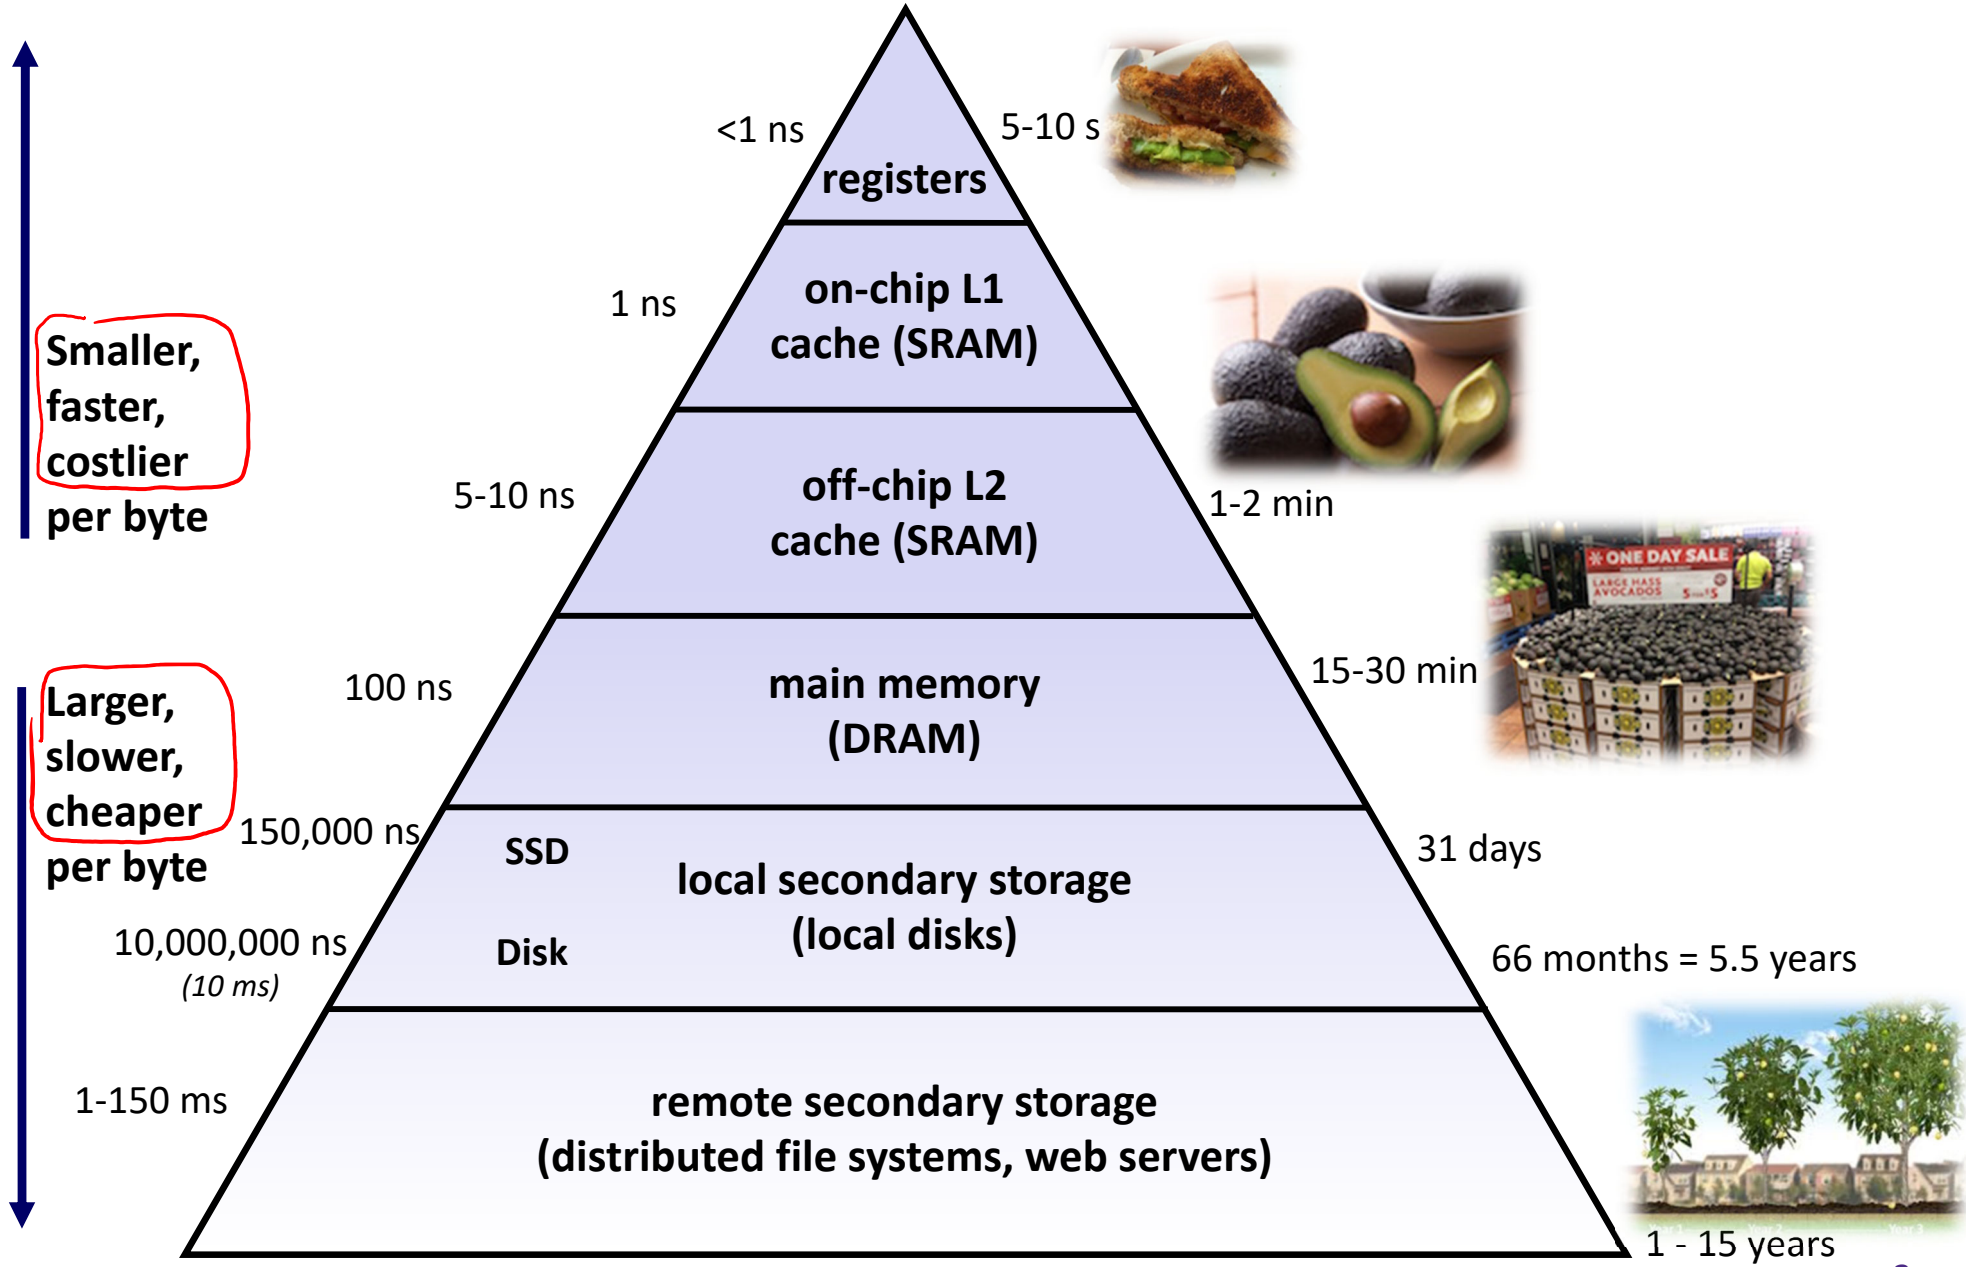
Andrew Hu
Antonio Castelli
Cosmo Wang
Diya Joy
Ivy Yu
Kaelin Laundry
Maurice Montag
Melissa Birchfield
Millicent Li
Suraj Jagadeesh

Administrivia

- hw15 due Wednesday, hw16 due *next* Wed (11/20)
  - Don't wait too long, this is a BIG hw (11.5 points)
- Lab 3 due Friday (11/8)

- **Mid-Quarter Survey Feedback**
  - Pace is "moderate" to "a bit too fast"
  - Lecture sometimes moves too quickly, especially at the end
  - Midterm was difficult and under significant time pressure
  - String matching on Gradescope quizzes is super frustrating

An Example Memory Hierarchy

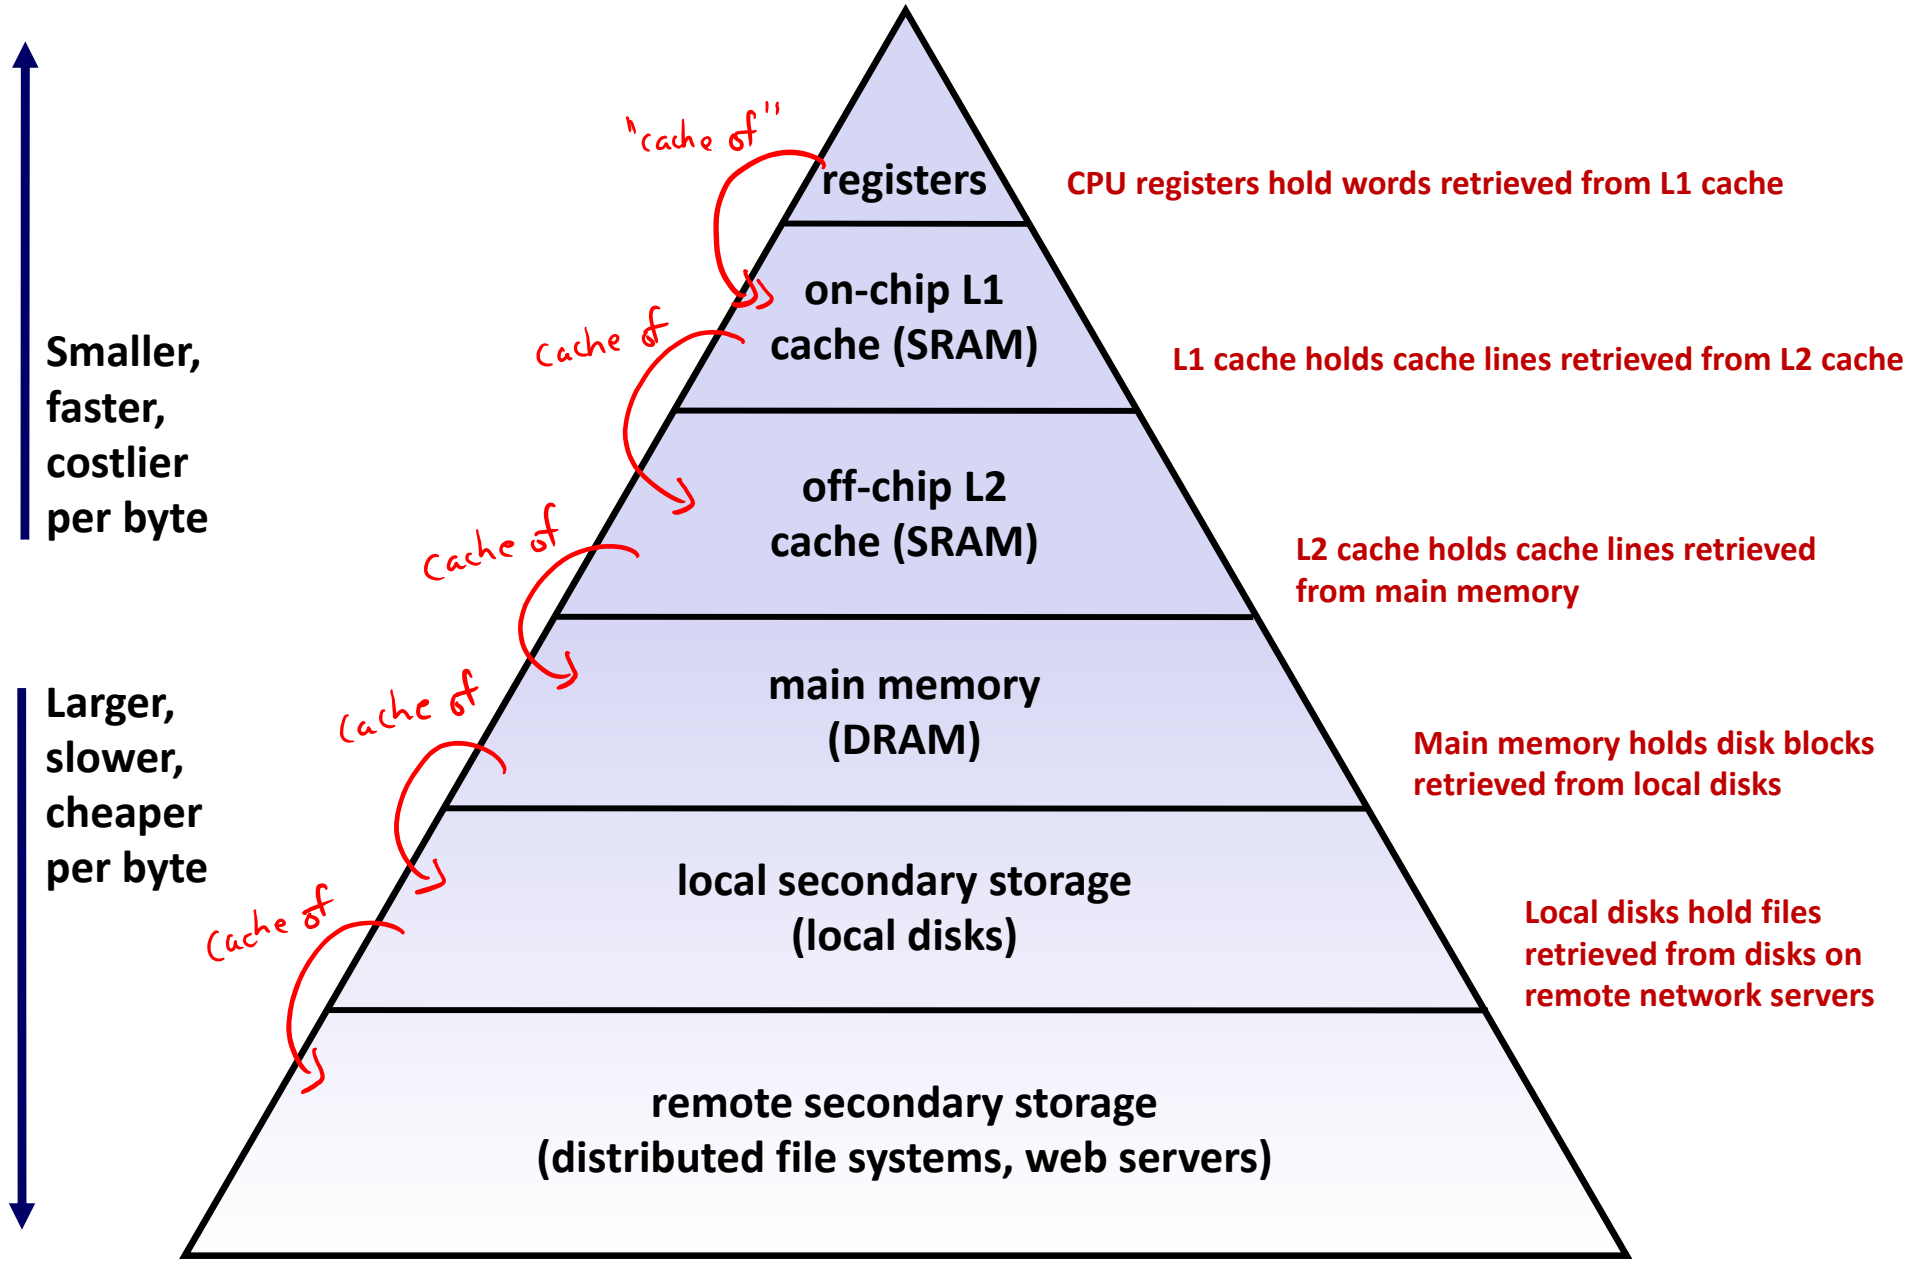


Memory Hierarchies

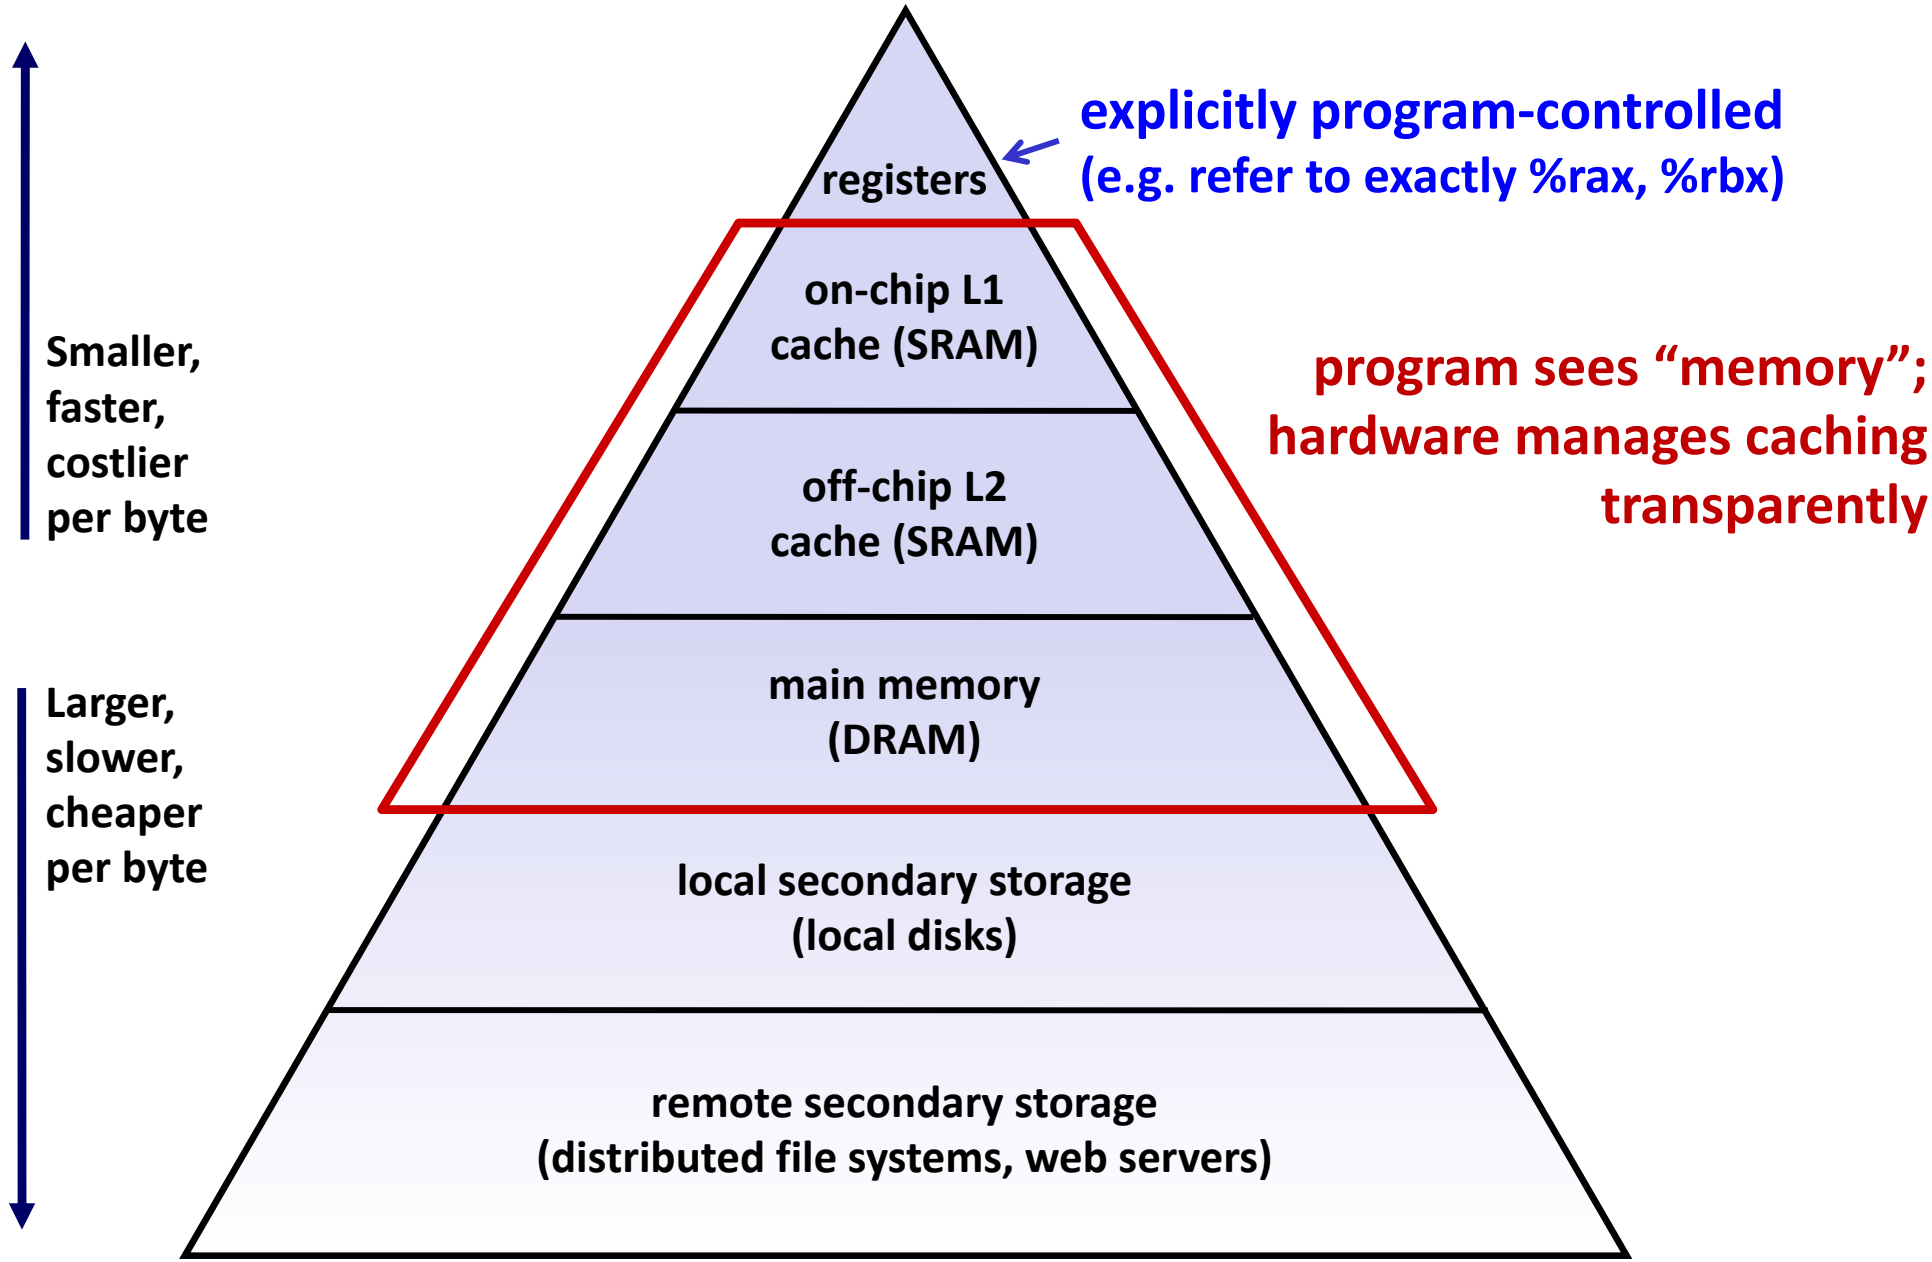
- Some fundamental and enduring properties of hardware and software systems:
  - Faster storage technologies almost always cost more per byte and have lower capacity
  - The gaps between memory technology speeds are widening
    - True for: registers ↔ cache, cache ↔ DRAM, DRAM ↔ disk, etc.
  - Well-written programs tend to exhibit good locality

- These properties complement each other beautifully
  - They suggest an approach for organizing memory and storage systems known as a memory hierarchy
    - For each level k, the faster, smaller device at level k serves as a cache for the larger, slower device at level k+1

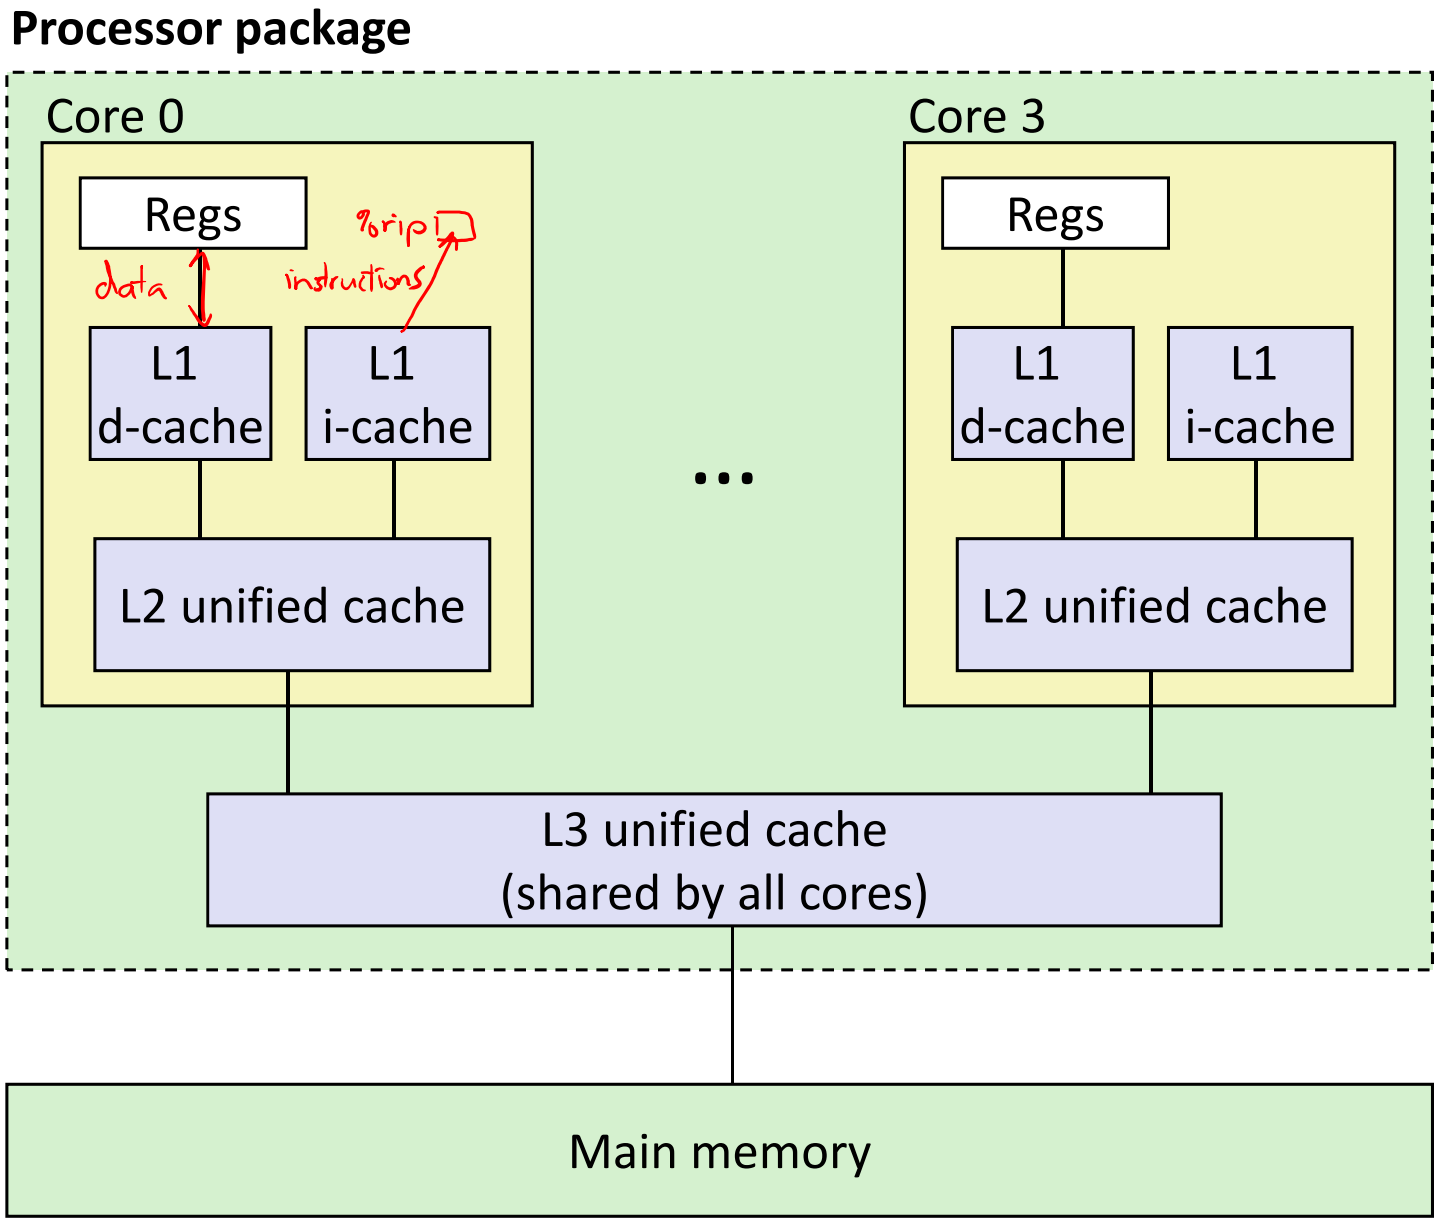
An Example Memory Hierarchy



An Example Memory Hierarchy



Intel Core i7 Cache Hierarchy



Block size:
64 bytes for all caches

L1 i-cache and d-cache:
32 KiB, 8-way,
Access: 4 cycles

L2 unified cache:
256 KiB, 8-way,
Access: 11 cycles

L3 unified cache:
8 MiB, 16-way,
Access: 30-40 cycles

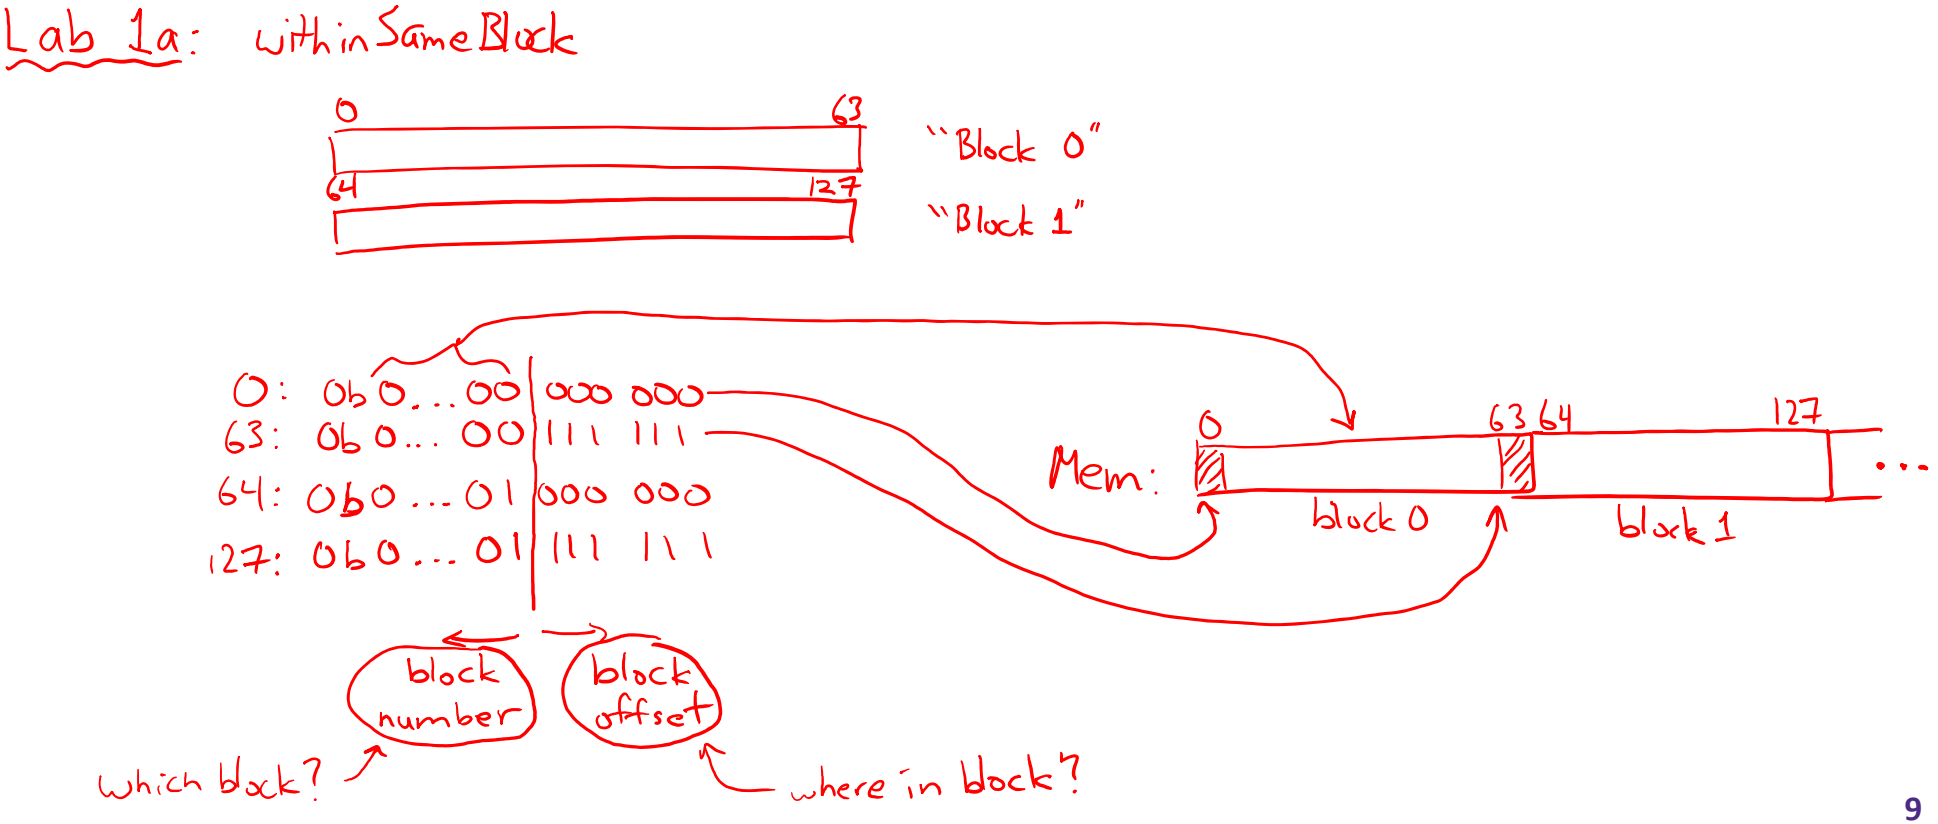
Making memory accesses fast!

- Cache basics
- Principle of locality
- Memory hierarchies
- **Cache organization**
  - **Direct-mapped (*sets*; index + tag)**
  - **Associativity (*ways*)**
  - Replacement policy
  - Handling writes
- Program optimizations that consider caches

Cache Organization (1)

Note: The textbook uses "B" for block size

- Block Size (K): unit of transfer between $ and Mem
  - Given in bytes and always a power of 2 (*e.g.* 64 B)
  - Blocks consist of adjacent bytes (differ in address by 1)
    - Spatial locality!



Cache Organization (1)

Note: The textbook uses "b" for offset bits

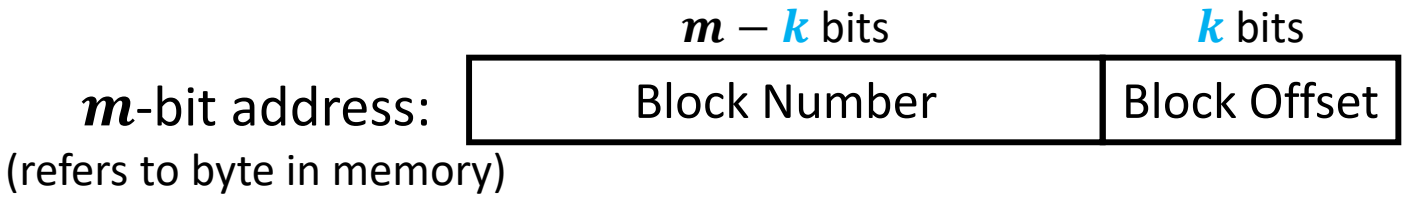
- Block Size (K): unit of transfer between $ and Mem
  - Given in bytes and always a power of 2 (*e.g.* 64 B)
  - Blocks consist of adjacent bytes (differ in address by 1)
    - Spatial locality!

$x \,\%\, 2^n$ = value of the lowest n bits

0b … 2^{n+1} 2^n 2^{n-1} … 2^1 2^0

- Offset field
  - Low-order $\log_2(K) = k$ bits of address tell you which byte within a block (64 → 6)
    - (address) mod 2^n = n lowest bits of address
  - (address) modulo (# of bytes in a block) (remainder)

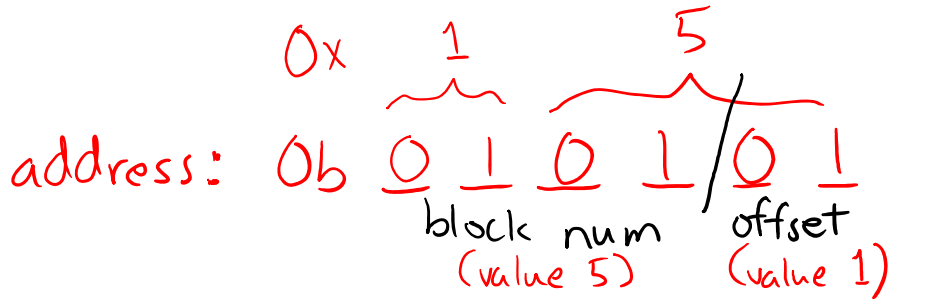
How many bits do I need to specify every byte in a block?



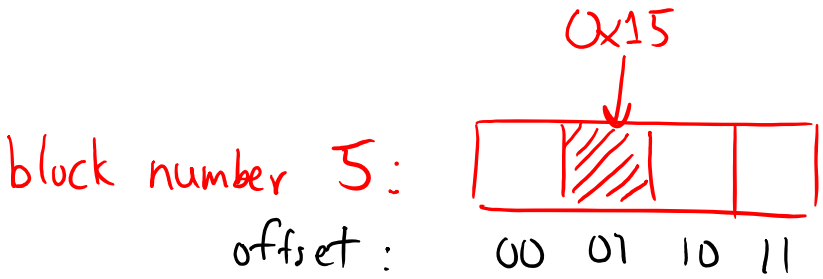
Polling Question

- If we have m 6-bit addresses and block size K = 4 B, which block and byte does 0x15 refer to?
  - Vote at: http://PollEv.com/justinh

	Block Num	Block Offset
A.	1	1
B.	1	5
C.	5	1
D.	5	5
E.	We're lost…	



offset width = $\log_2(K) = \log_2(4) = 2$ bits



Cache Organization (2)

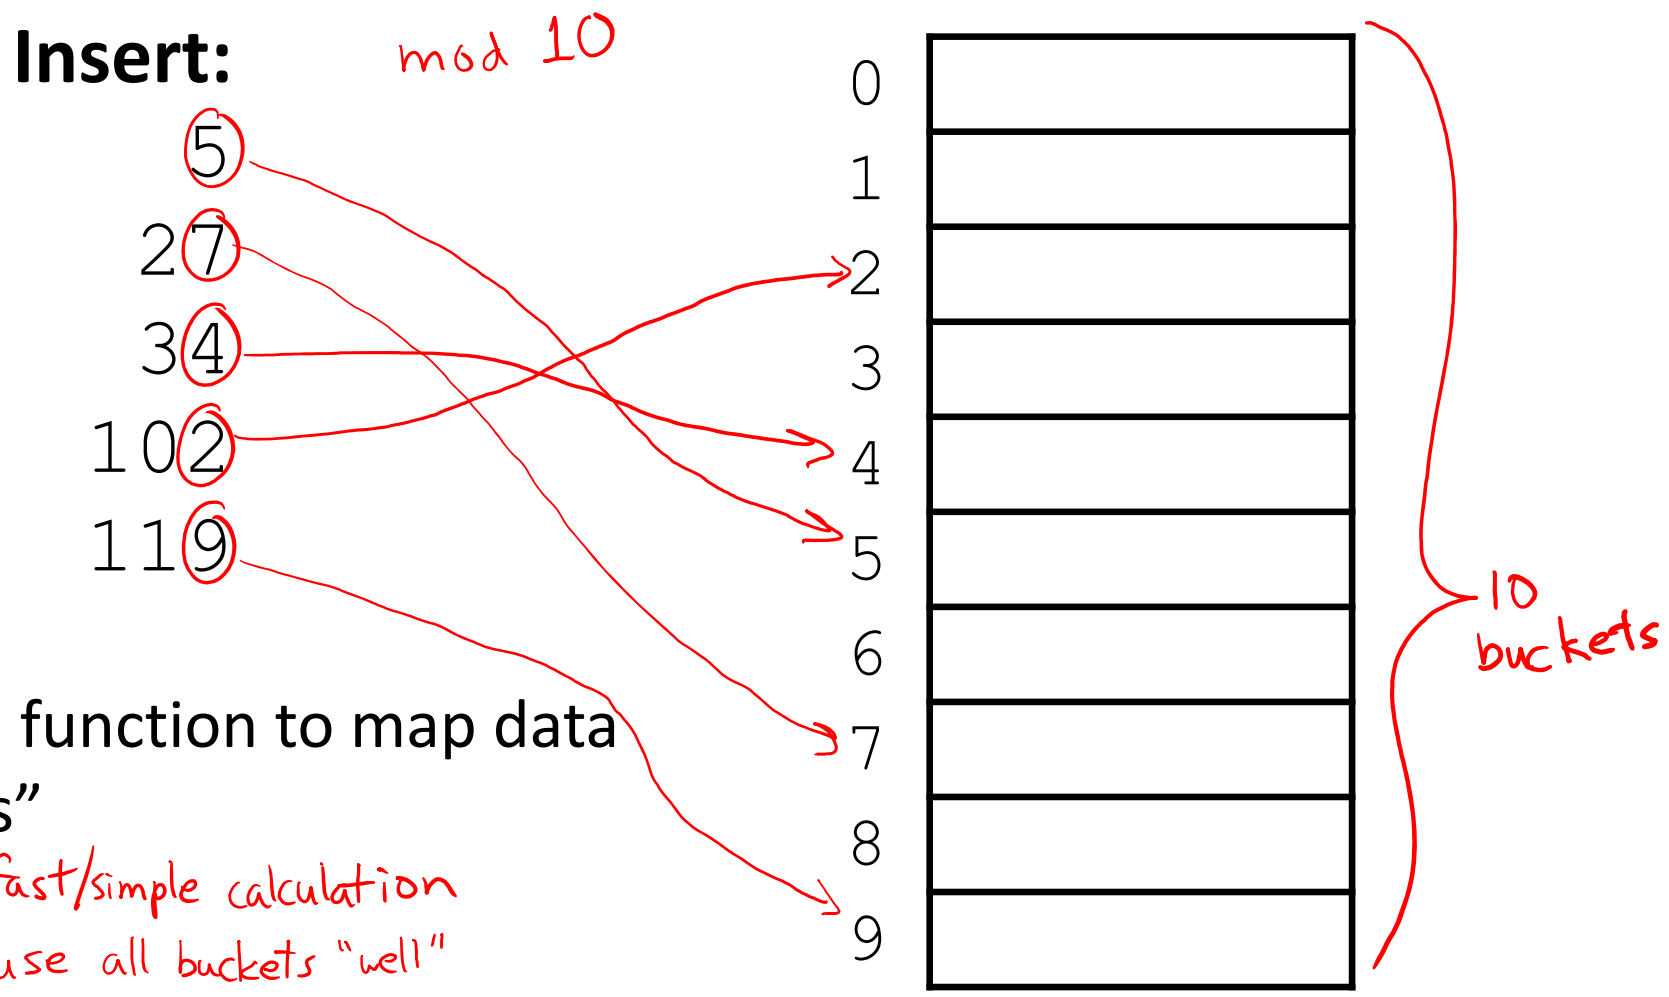
- Cache Size (C): amount of *data* the $ can store
  - Cache can only hold so much data (subset of next level)
  - Given in bytes (C) or number of blocks (C/K)
  - Example: C = 32 KiB = 512 blocks if using 64-B blocks

$2^5 \times 2^{10} = 2^{15}$ B $\times \frac{1 \text{ block}}{2^6 \text{ B}} = 2^9$ blocks

- Where should data go in the cache?
  - We need a mapping from memory addresses to specific locations in the cache to make checking the cache for an address **fast**

- What is a data structure that provides fast lookup?
  - Hash table!

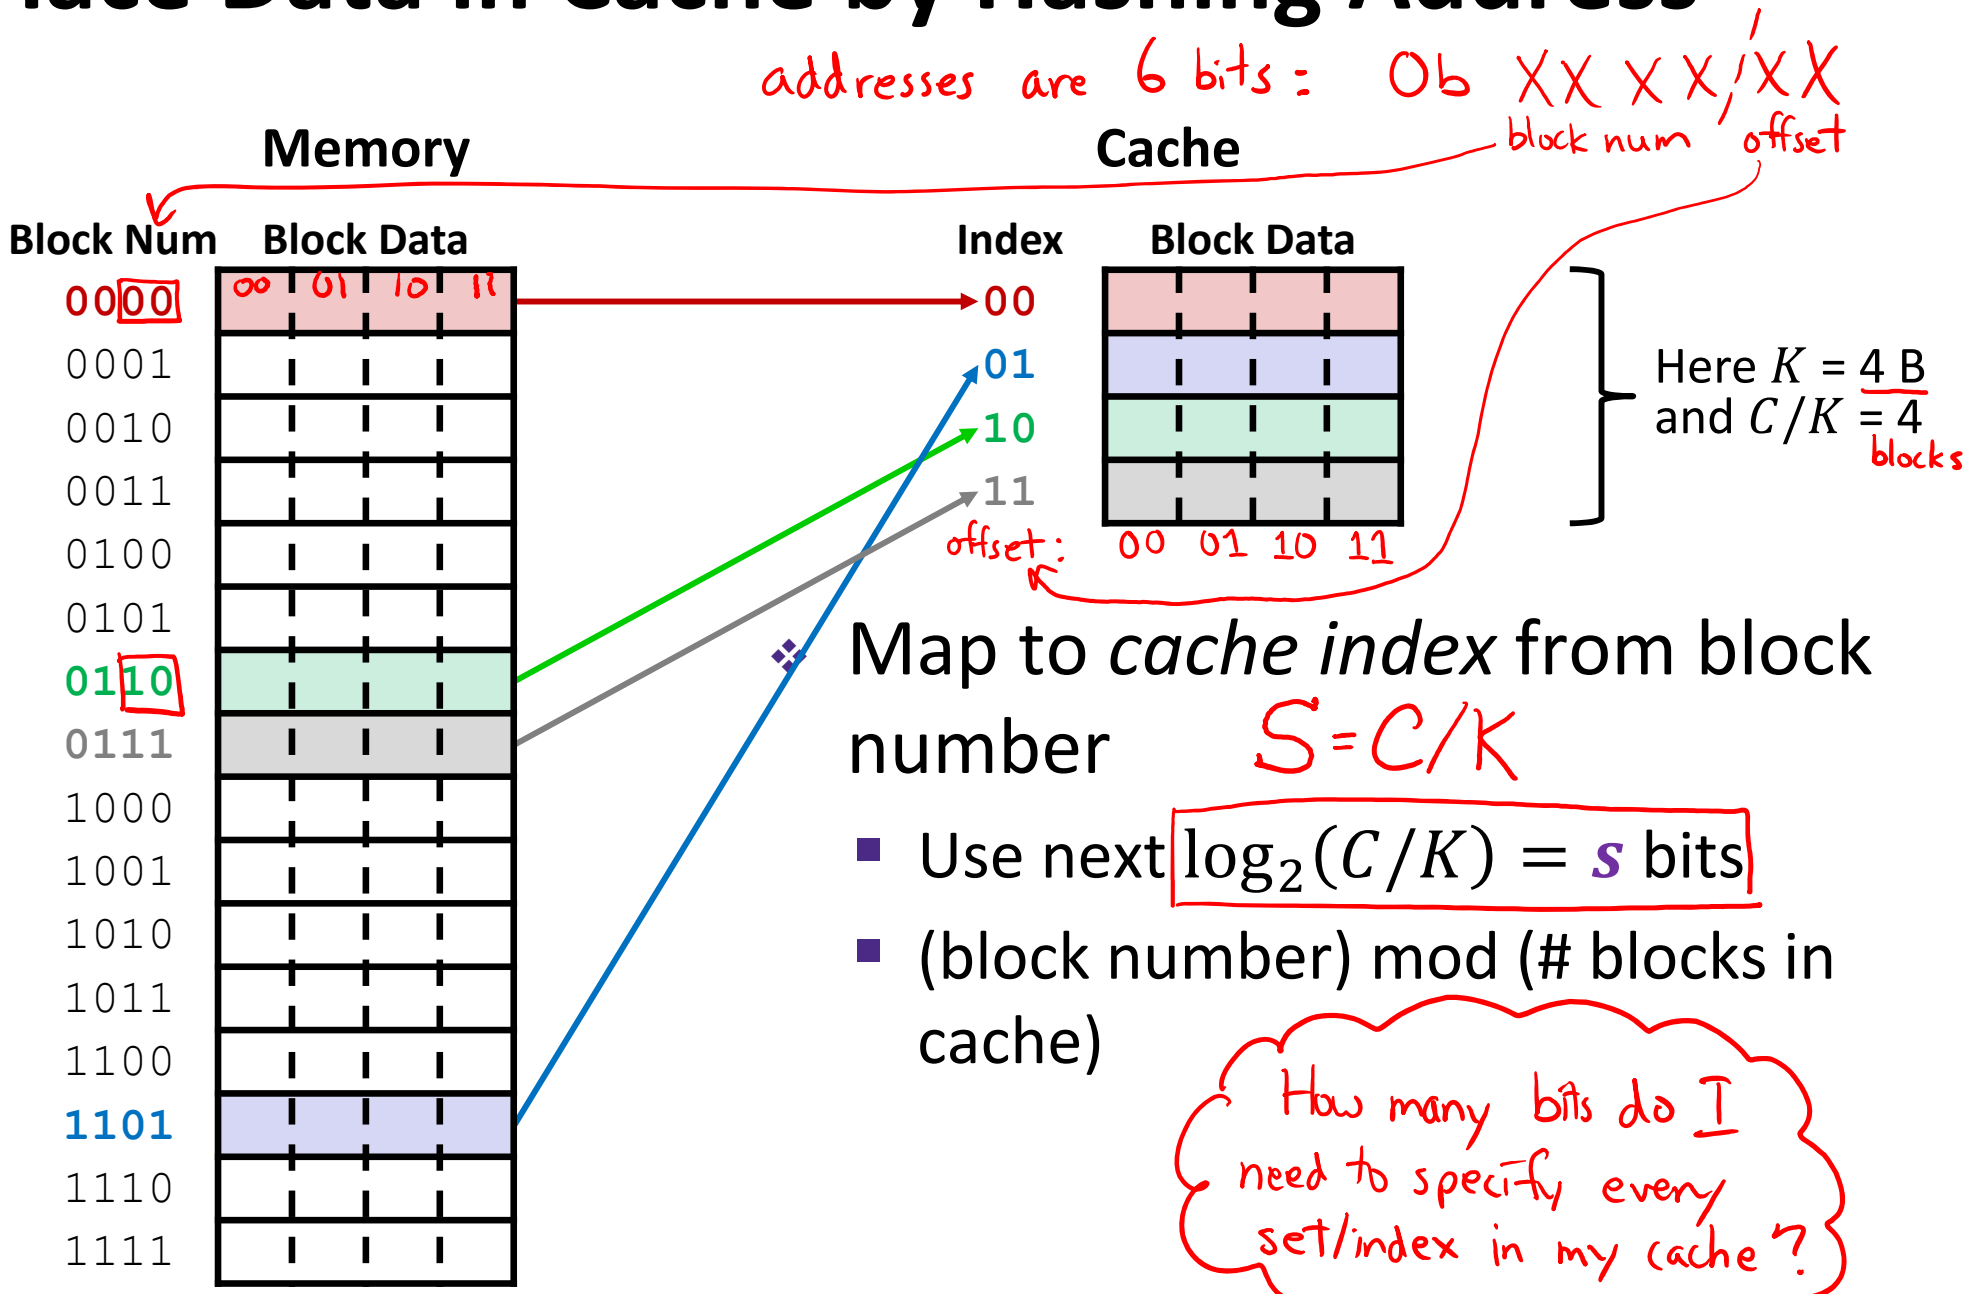
Review: Hash Tables for Fast Lookup



Apply hash function to map data to "buckets"

Goals: ① fast/simple calculation
② use all buckets "well"

Place Data in Cache by Hashing Address

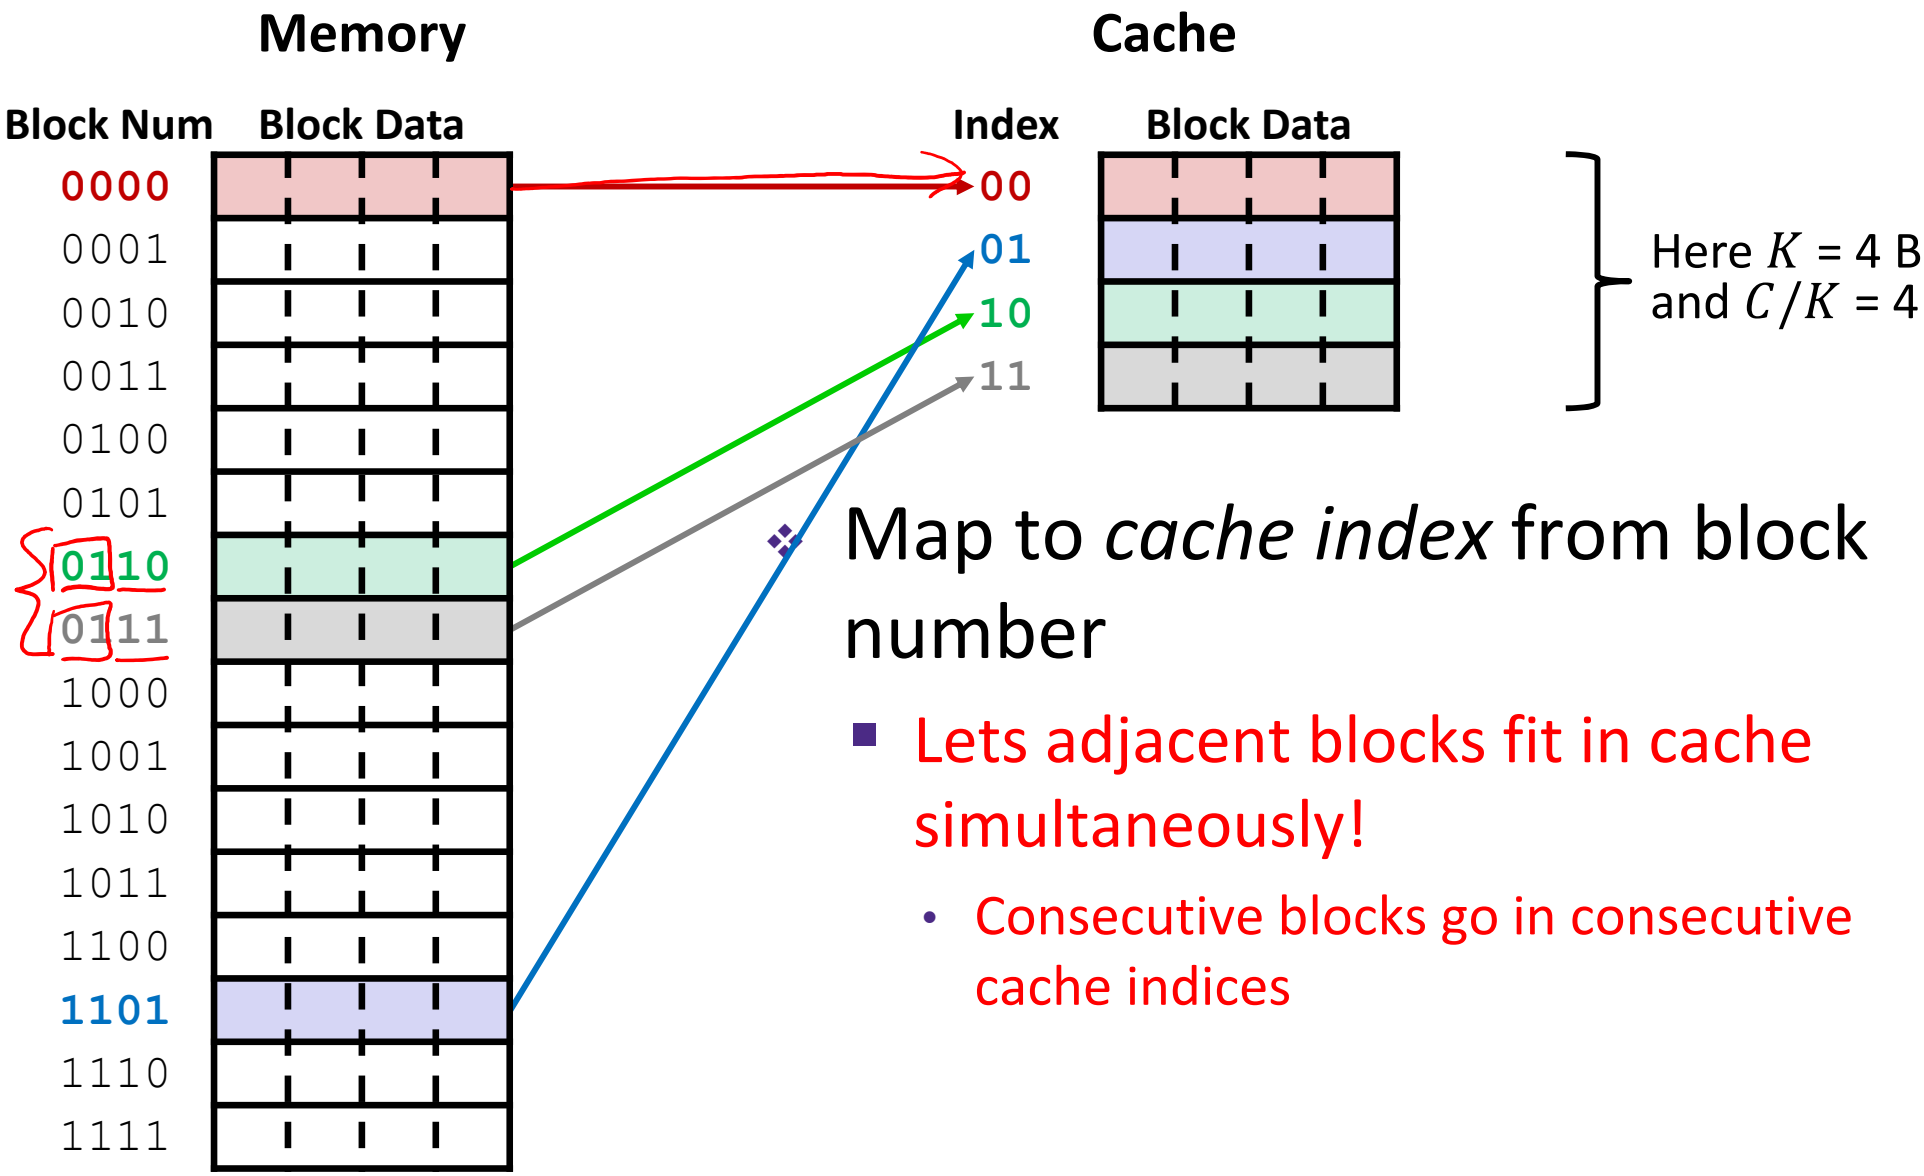


Map to *cache index* from block number $S = C/K$

- Use next $\log_2(C/K) = s$ bits
- (block number) mod (# blocks in cache)

How many bits do I need to specify every set/index in my cache?

Place Data in Cache by Hashing Address

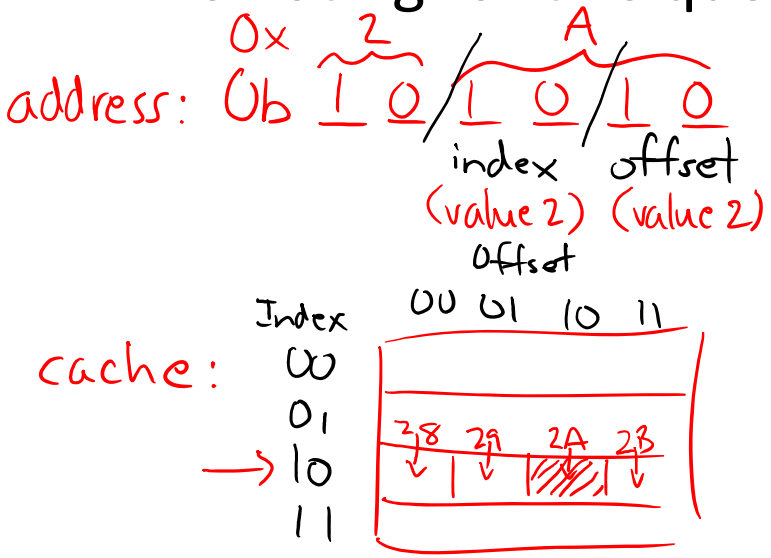


Map to *cache index* from block number

- Lets adjacent blocks fit in cache simultaneously!
  - Consecutive blocks go in consecutive cache indices

Practice Question

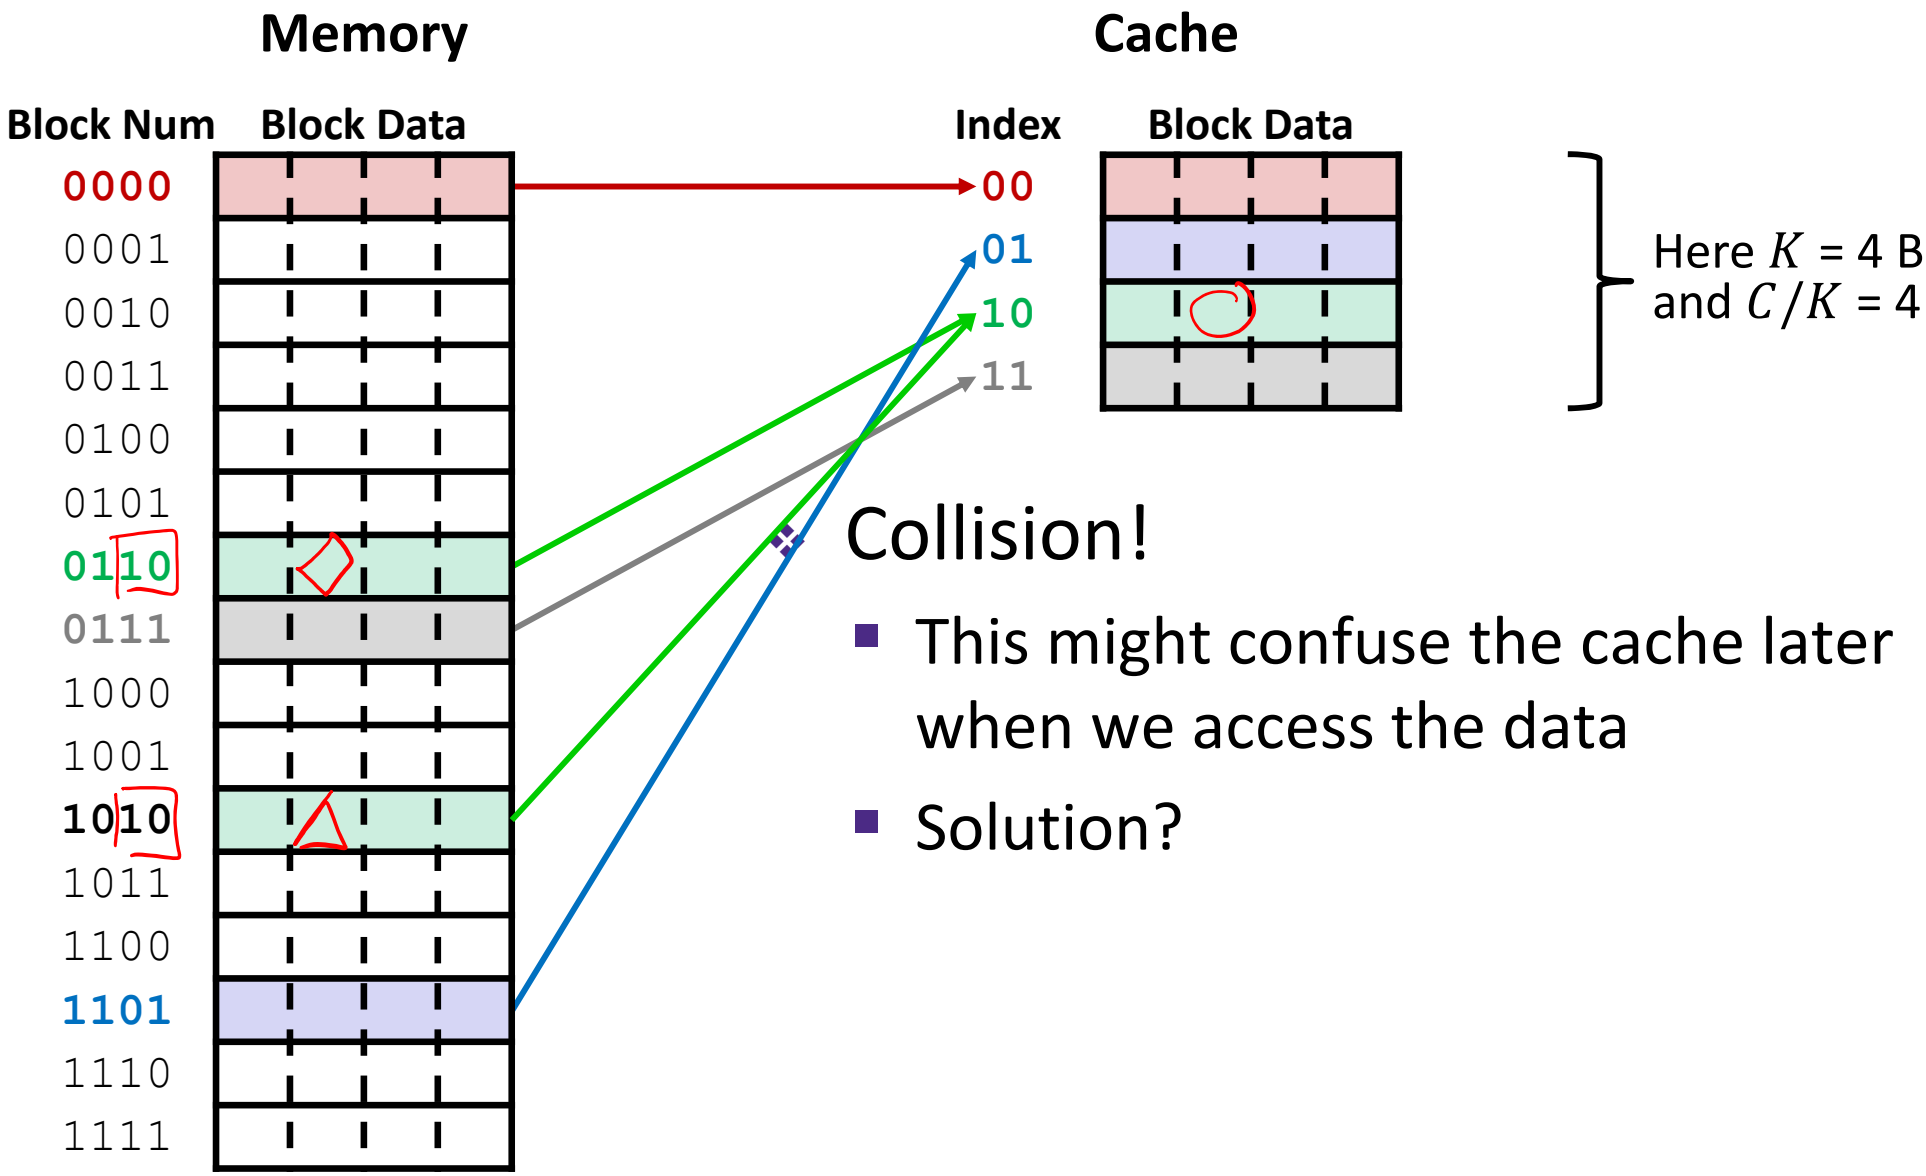
- 6-bit addresses, block size K = 4 B, and our cache holds S = 4 blocks. $= C/K$, $s = \log_2(4) = 2$ bits
- A request for address **0x2A** results in a cache miss. Which index does this block get loaded into and which 3 other addresses are loaded along with it?
  - No voting for this question



Index 2 (0b10)

along with: 0b1010 00 = 0x28
01 = 0x29
11 = 0x2B

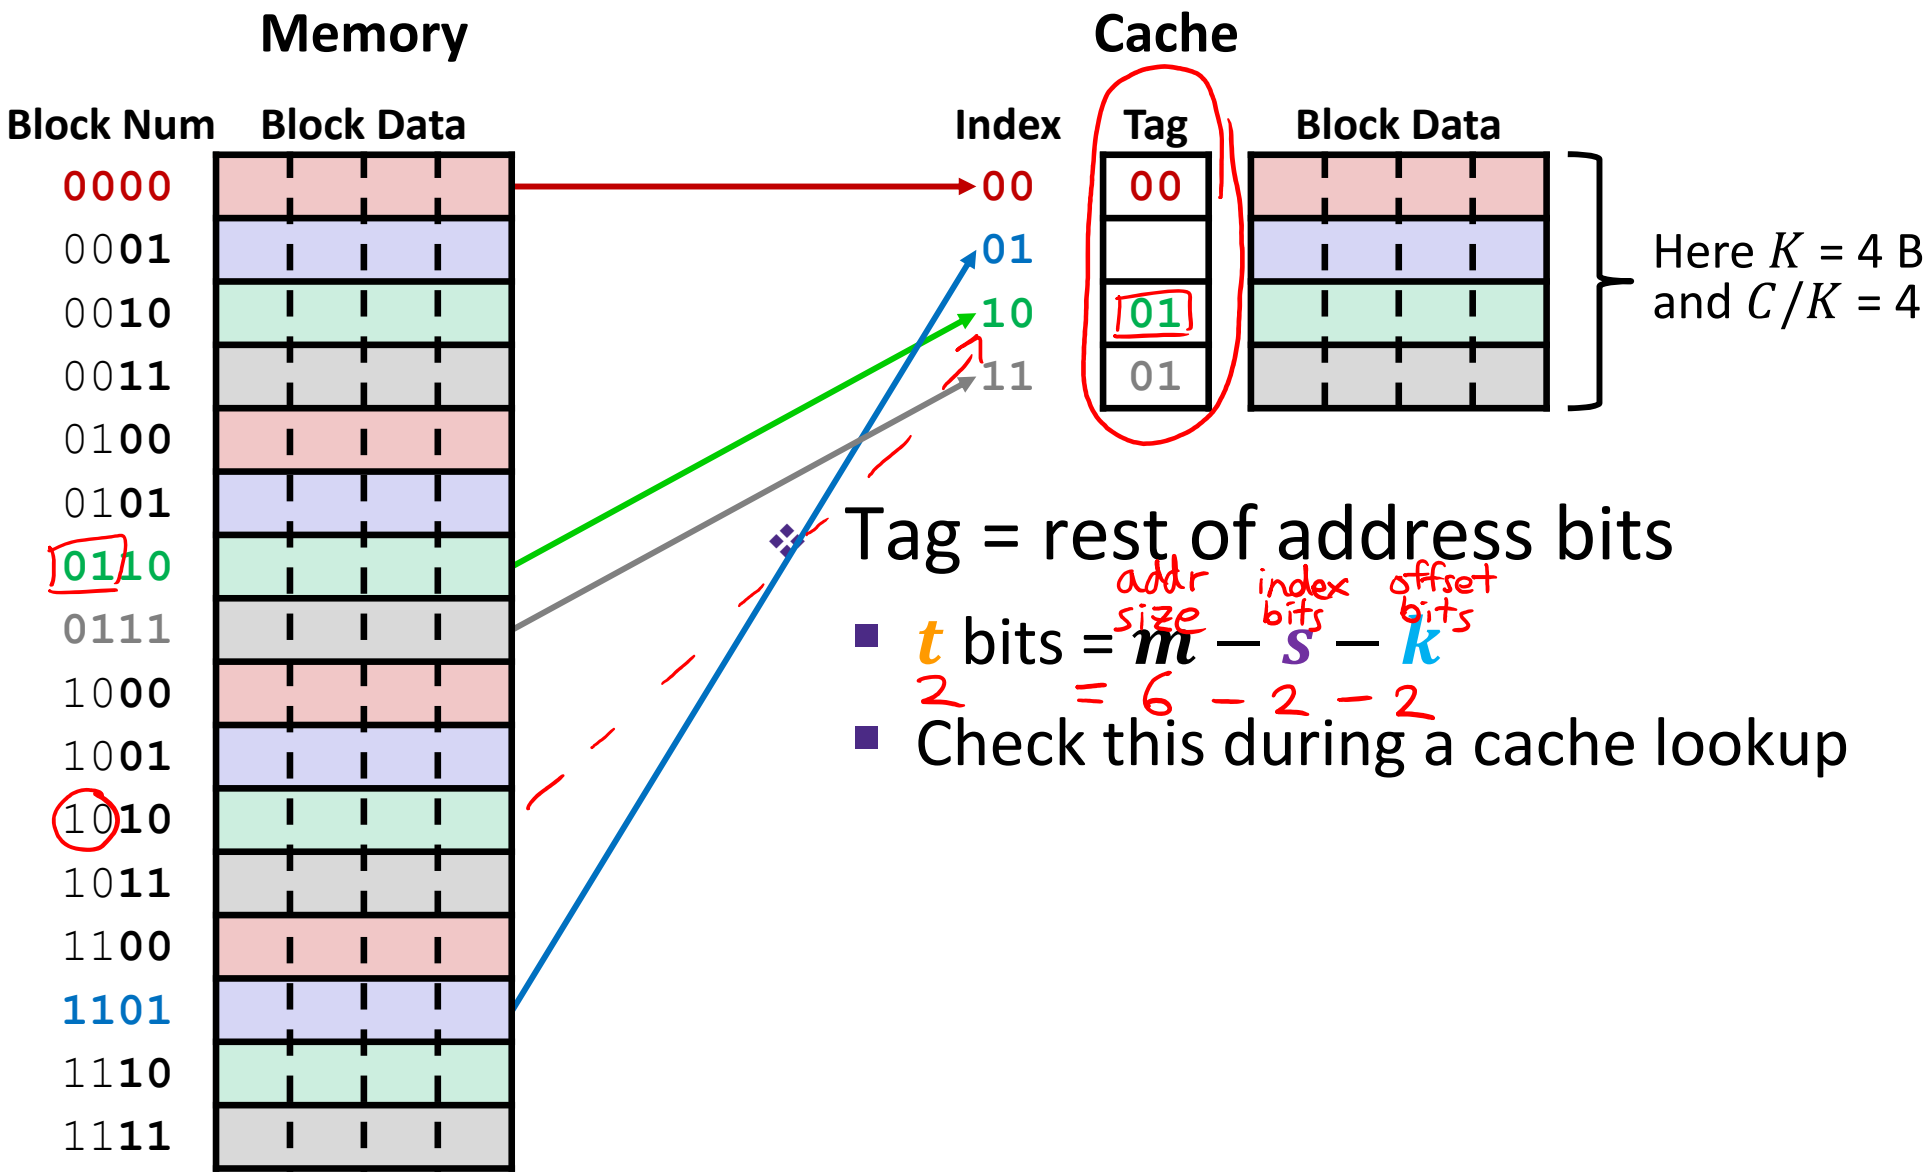
Place Data in Cache by Hashing Address



Collision!

- This might confuse the cache later when we access the data
- Solution?

Tags Differentiate Blocks in Same Index

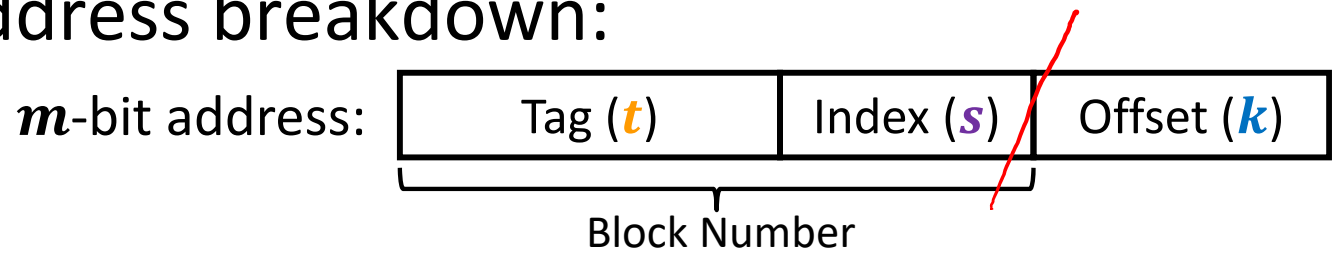


- Tag = rest of address bits
  - t bits = $m - s - k$ (addr size − index bits − offset bits)
  - 2 = 6 − 2 − 2
- Check this during a cache lookup

Checking for a Requested Address

- CPU sends address request for chunk of data
  - Address and requested data are not the same thing!
    - Analogy: your friend ≠ his or her phone number

- TIO address breakdown:



1. **Index** field tells you where to look in cache
2. **Tag** field lets you check that data is the block you want
3. **Offset** field selects specified start byte within block

- **Note:** t and s sizes will change based on hash function

Cache Puzzle

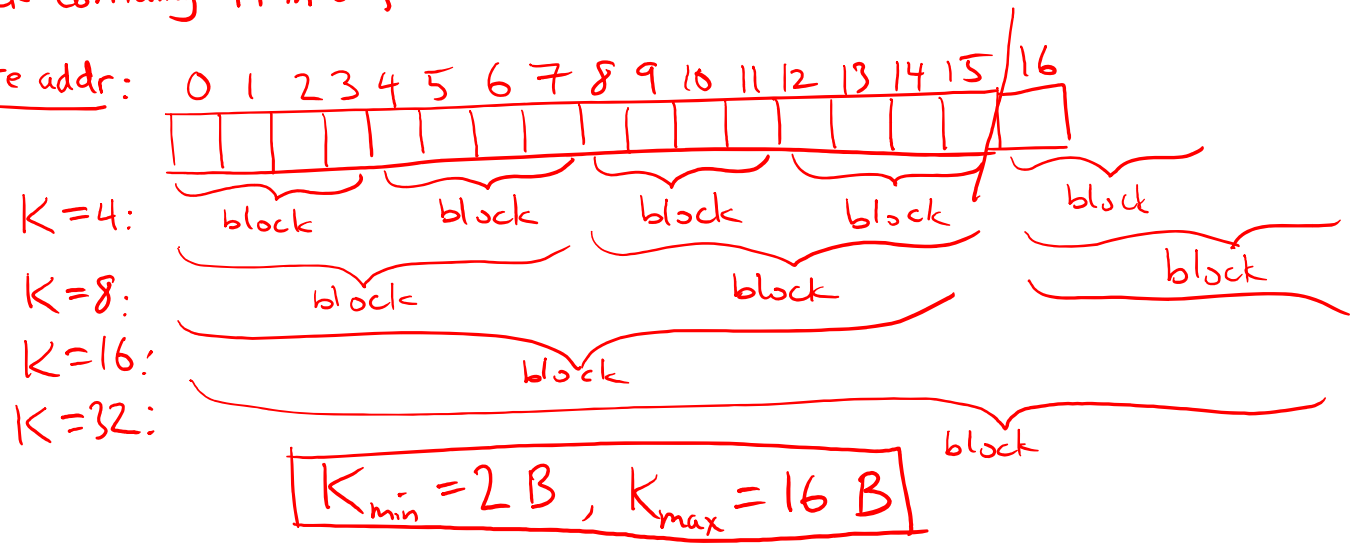
Vote at http://PollEv.com/justinh

- Based on the following behavior, which of the following block sizes is NOT possible for our cache?
  - Cache starts *empty*, also known as a *cold cache*
  - Access (addr: hit/miss) stream:
    - (14: miss), (15: hit), (16: miss)

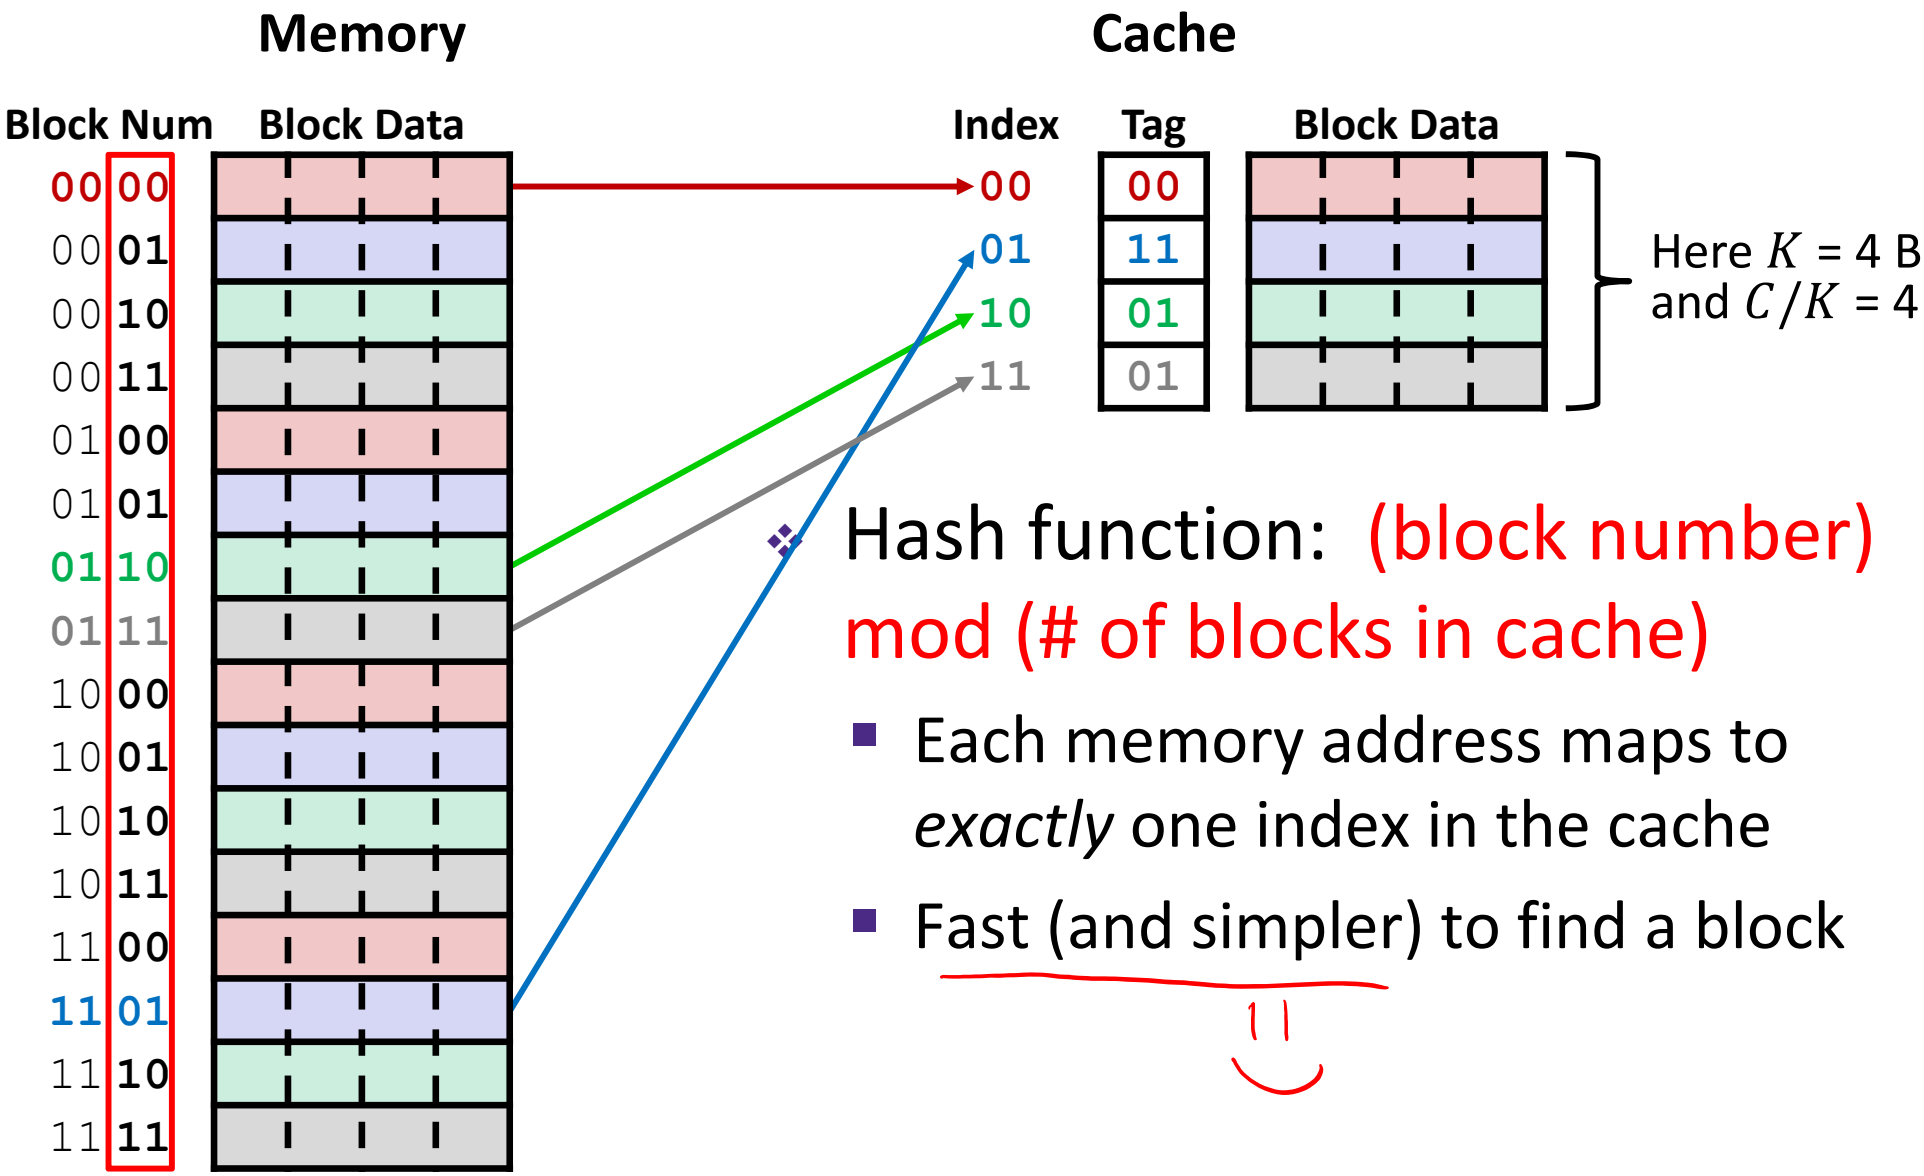
hit: block with data already in $
miss: data not in $, pulls block containing data from Mem

↳① pulls block containg 14 into $
↳② 14 & 15 are in the same block
↳③ 16 is in a different block

A. 4 bytes
B. 8 bytes
C. 16 bytes
D. 32 bytes
E. We're lost…



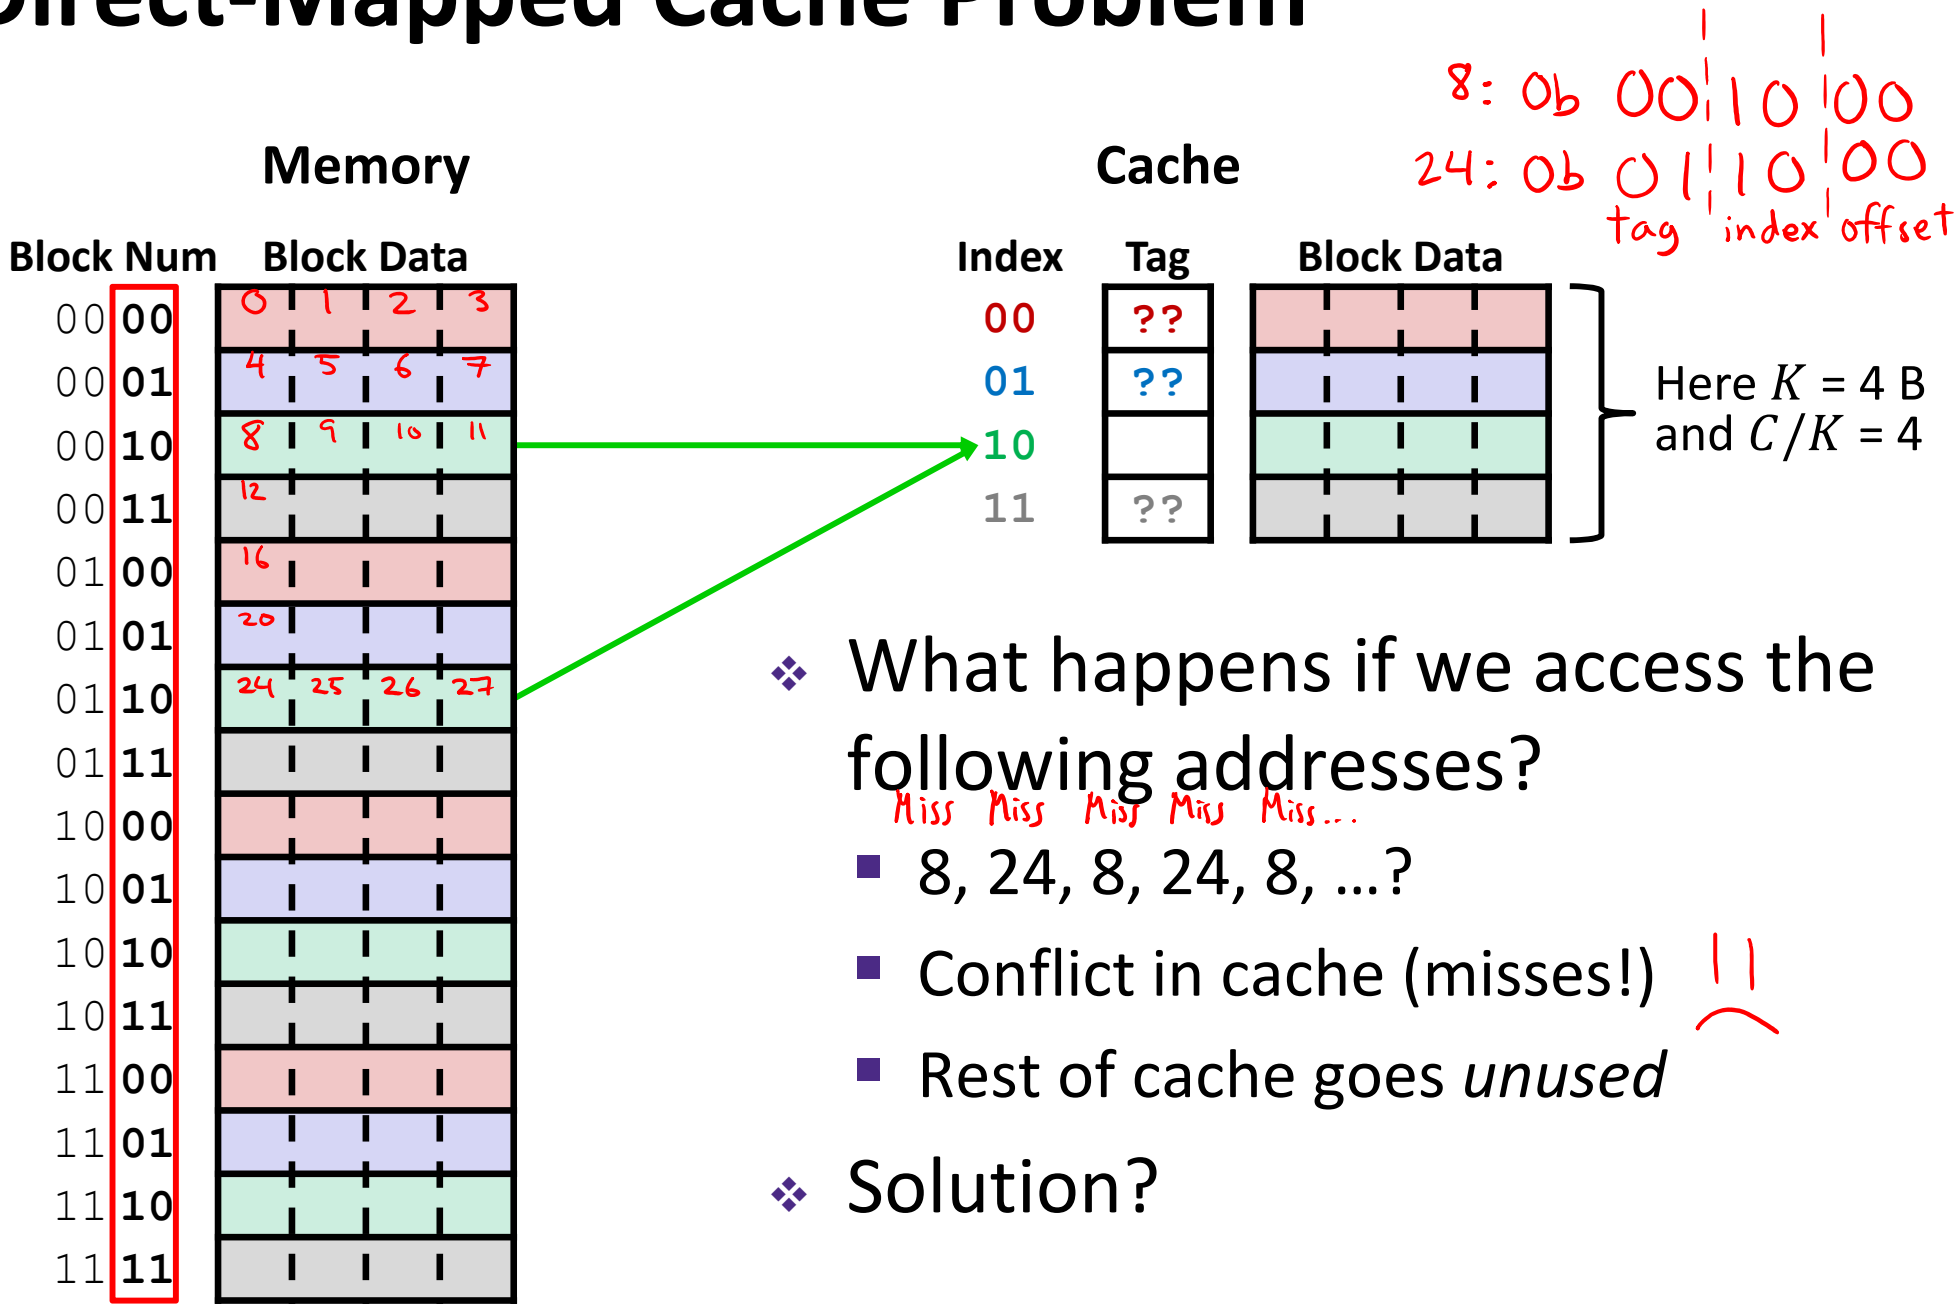
Direct-Mapped Cache



Hash function: (block number) mod (# of blocks in cache)

- Each memory address maps to *exactly* one index in the cache
- Fast (and simpler) to find a block

Direct-Mapped Cache Problem



- What happens if we access the following addresses?
  Miss Miss Miss Miss Miss...
  - 8, 24, 8, 24, 8, …?
  - Conflict in cache (misses!)
  - Rest of cache goes *unused*
- Solution?
