# CSE 351 Section 5 – Arrays and Structs

Welcome back to section, we're happy that you're here ☺

## Arrays

- Arrays are contiguously allocated chunks of memory large enough to hold the specified number of elements of the size of the datatype. Separate array allocations are not guaranteed to be contiguous.
- 2-dimensional arrays are allocated in row-major ordering in C (i.e. the first row is contiguous at the start of the array, followed by the second row, etc.).
- 2-level arrays are formed by creating an array of pointers to other arrays (i.e. the second level).

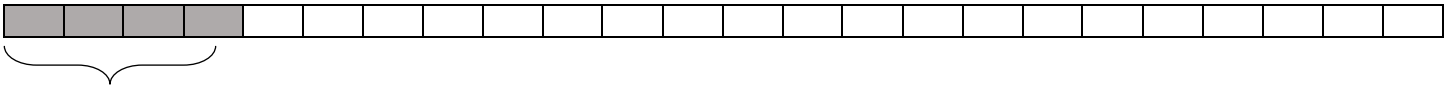
## Structs

- Structs are contiguously allocated chunks of memory that hold a programmer-defined collection of potentially disparate variables.
- Individual fields appear in the struct in the order that they are declared
- Each field follows its variable alignment requirement, with internal fragmentation added between fields as necessary.
- The overall struct is aligned according to the largest field alignment requirement, with external fragmentation added at the end as necessary.

---

```
struct Student {
  int id;
  char* name;
  char age;
};
```

a) Fill in which bytes are used by which variables and label the rest as internal or external fragmentation. The first variable "id" is given.



`id`

b) What is the size of `struct Student`?

c) Give a reordering of the fields in `struct Student` such that there is no internal fragmentation

```
struct Student {

};
```

d) How much external fragmentation does this new `struct Student` have?

e) What is the size of this new `struct Student`?

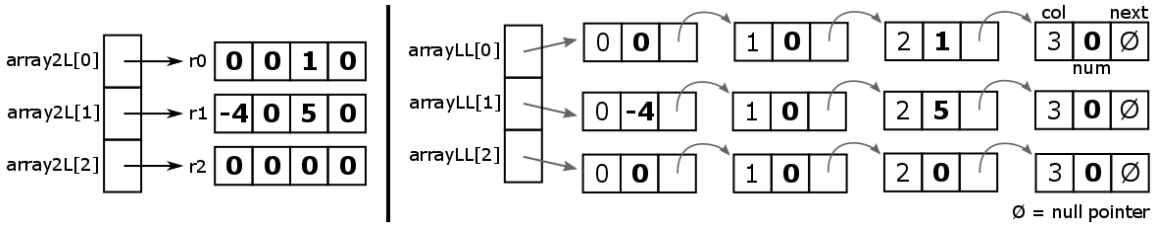
We have a two-dimensional matrix of integer data of size $M$ rows and $N$ columns. We are considering 3 different representation schemes:

1) 2-dimensional array `int array2D[][]`, // M*N array of ints
2) 2-level array `int* array2L[]`, and // M array of int arrays
3) array of linked lists `struct node* arrayLL[]`. // M array of linked lists (struct node)

Consider the case where $M = 3$ and $N = 4$. The declarations are given below:

| **2-dimensional array:** | **2-level array:** | **Array of linked lists:** |
|---|---|---|
| `int array2D[3][4];` | `int r0[4], r1[4], r2[4];`<br>`int* array2L[] = {r0,r1,r2};` | `struct node {`<br>`  int col, num;`<br>`  struct node* next;`<br>`};`<br>`struct node* arrayLL[3];`<br>`// code to build out LLs` |

For example, the diagrams below correspond to the matrix $\begin{bmatrix} 0 & 0 & 1 & 0 \\ -4 & 0 & 5 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ for `array2L` and `arrayLL`:



a) Fill in the following comparison chart:

| | 2-dim array | 2-level array | Array of LLs: |
|---|---|---|---|
| Overall Memory Used | | | |
| Largest *guaranteed* continuous chunk of memory | | | |
| Smallest *guaranteed* continuous chunk of memory | | | |
| Data type returned by: | `array2D[1]` | `array2L[1]` | `arrayLL[1]` |
| Number of memory accesses to get `int` in the *BEST* case | | | |
| Number of memory accesses to get `int` in the *WORST* case | | | |

b) Sam Student claims that since our arrays are relatively small ($N < 256$), we can save space by storing the `col` field as a char in `struct node`. Is this correct? If so, how much space do we save? If not, is this an example of *internal* or *external* fragmentation?

c) Provide a scenario where a 2-dimensional array would be more useful and another where a 2-level array would be more useful.

d) Sam wants to create a 2-D matrix of the countries of the world that can be accessed alphabetically. Which implementation should Sam choose to represent this information? Describe what this implementation would look like.

$$\begin{bmatrix} Afghanistan & Albania & \dots & Azerbaijan \\ Bahamas & \dots & Burundi & --- \\ \vdots & \vdots & \vdots & \vdots \\ Zambia & Zimbabwe & --- & --- \end{bmatrix}$$
