Signature indicating: All work is my own. I had no prior knowledge of the exam contents nor will I share contents with others in CSE351 who haven’t taken it yet. Violation of these terms could result in a failing grade.

Rules:
- The exam is closed-book, closed-note, etc.
- But it contains two useful reference pages at the end that were also posted in advance. Please remove this last piece of paper and do not turn it in.
- Please stop promptly at 12:20.
- There are 100 points, distributed unevenly among 6 questions (all with multiple parts):
- The exam is printed double-sided.

Advice:
- Read questions carefully. Understand a question before you start writing.
- Write down thoughts and intermediate steps so you can get partial credit. But clearly indicate what is your final answer.
- The questions are not necessarily in order of difficulty. Skip around. Make sure you get to all the questions.
- If you have questions, ask.
- Relax. You are here to learn.
1. **(18 points) (32-Bit Integers and Bit Operations)**

   (a) In hex notation, write +30 (base-10) as a 32-bit twos-complement number.

   (b) In hex notation, write -30 (base-10) as a 32-bit twos-complement number.

   (c) In hex notation, write the most-positive 32-bit twos-complement number.

   (d) In hex notation, write the most-negative 32-bit twos-complement number.

Now suppose x is a C `int` and a signed 32-bit twos-complement number. For each of the following C expressions answer:

- *always zero* if the expression evaluates to 0 for every value of x
- *sometimes zero* if the expression evaluates to 0 for some values of x but not all values of x
- *never zero* if the expression evaluates to 0 for no values of x

(e) \((\neg x) \mid x\)

(f) \((x \ll 1) \& !x\)

(g) \((x \& 0x00FF) \wedge (x \& 0xFF00)\)

(h) \(x \& (x \ll 1)\)

(i) \(\neg x + x + 1\)
2. (18 points) (Pointers, Arrays, and C) For this problem assume:

- int is 4 bytes
- char is 1 byte
- machine is little-endian
- The array a begins at address 0x100.

Throughout this problem, if any byte of memory holds 0, you can leave it blank — this saves you some writing if you wish.

Consider this C code, which does nothing useful:

```c
int a[6];
for(int i=0; i < 6; i++) {
    a[i] = i;
}
// part a
int * ip = a;
for(int i=0; i < 6; i++) {
    *ip = *ip + 2;
    ip++;
}
// part b
char * cp = (char *) a;
for(int i=0; i < 6; i++) {
    *cp = *cp + 2;
    cp++;
}
// part c
a[0] = a[0] + a[1] + a[2];
// part d
```

(a) What is the value of each byte of a when control reaches the line // part a? Enter a hex value in each (non-zero) square below — you don’t need to write 0x.

```
0x100 0x101 0x102 0x103 0x104 0x105 0x106 0x107 0x108 0x109 0x10A 0x10B 0x10C 0x10D 0x10E 0x10F 0x110 0x111 0x112 0x113 0x114 0x115 0x116 0x117
```

(b) What is the value of each byte of a when control reaches the line // part b? Enter a hex value in each (non-zero) square below — you don’t need to write 0x.

```
0x100 0x101 0x102 0x103 0x104 0x105 0x106 0x107 0x108 0x109 0x10A 0x10B 0x10C 0x10D 0x10E 0x10F 0x110 0x111 0x112 0x113 0x114 0x115 0x116 0x117
```

(c) What is the value of each byte of a when control reaches the line // part c? Enter a hex value in each (non-zero) square below — you don’t need to write 0x.

```
0x100 0x101 0x102 0x103 0x104 0x105 0x106 0x107 0x108 0x109 0x10A 0x10B 0x10C 0x10D 0x10E 0x10F 0x110 0x111 0x112 0x113 0x114 0x115 0x116 0x117
```

(d) What is the value of each byte of a when control reaches the line // part d? Enter a hex value in each (non-zero) square below — you don’t need to write 0x.

```
0x100 0x101 0x102 0x103 0x104 0x105 0x106 0x107 0x108 0x109 0x10A 0x10B 0x10C 0x10D 0x10E 0x10F 0x110 0x111 0x112 0x113 0x114 0x115 0x116 0x117
```
3. (17 points) (Floating-Point Numbers)
Throughout this problem, we assume single-precision (i.e., 32-bit) IEEE-754 floating-point numbers.

(a) Consider the decimal number 10.75. Give the IEEE-754 representation of this number filling in the diagram below. Hint: Remember bias and the implicit bit. Consider explaining your work for potential partial credit but explanation is not required.

```
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
```

(b) Consider the range of numbers between 2.0 and 12.0.
   i. What is the smallest gap between any two representable numbers in this range? (You can give your answer in the form $a^b$. For example, $3^{-5}$ would be in this form.)

   ii. What is the largest gap between any two representable numbers in this range? (Again you can give your answer in the form $a^b$.)

   iii. If $x$ and $y$ are two representable numbers in this range and we subtract them, will we get rounding error? Answer yes if there will be rounding error for all such $x$ and $y$, maybe if it depends on $x$ and $y$, and no if rounding error is impossible.

   iv. Repeat the previous rounding-error question but assume $x$ and $y$ are two representable numbers in the range between 10.0 and 12.0.

(c) Consider this C code:
```c
void floaty_mcfloatface(float x) {
    float inf = 3.0 / 0.0; // positive infinity
    while(x < inf) {
        x += 1.0;
    }
}
```

If we call this function with a “normal” floating-point number for $x$ (ignore infinities, NaN, etc.), will it terminate ("yes" for always, “maybe” for depends on $x$, “no” for never)? Explain your answer in approximately 1–2 English sentences.
4. (15 points) (x86-64 Assembly) This problem considers this assembly implementation of a C function of the form long mystery(long x) { ... }

```
mystery:
movq $0, %rax

testq %rdi, %rdi
jle .L2
.L1:
addq %rdi, %rdi
addq $1, %rax

testq %rdi, %rdi
jg .L1
.L2:
ret
```

In parts (a)-(c) we ask you to modify the assembly code in ways that have **no effect** on the answers it produces, i.e., it should perform the same overall computation after any of your changes.

(a) Give a use of a **cmpq** instruction that could be used instead of either of the **testq** instructions.

(b) Give a use of a **shlq** instruction could be used instead of one of the **addq** instructions and indicate which instruction it is replacing.

(c) Suppose we replace the `jle .L2` with `jg .L1`. Insert an additional instruction to complete this change correctly: indicate what instruction you are adding and where.

Now we ask about what **mystery** is actually computing.

(d) Complete this description of what **mystery** computes with 1–2 English sentences: “It takes the number in %rdi and returns...”.

(e) What is the largest number **mystery** could possibly return? Answer in base-10.
5. (25 points) (Assembly, Procedures, Stacks) This problem considers an assembly implementation of these two C functions:

```c
long f(long s) {
    long y = s;
    g(&y,3);
    return y;
}

void g(long * p, long i) {
    if(i==0)
        return;
    *p += i;
    g(p,i-1);
    *p += i;
}
```

(a) What does \( f(7) \) return?

(b) Fill in the blanks to complete these implementations of \( f \) and \( g \) in assembly. Note some blanks give the instruction but not the operand(s) and others you choose both instruction and operand(s).

```
f:
pushq %rdi
movq _______, %rdi
movq _______, _______
call g
____________________
ret
```

```
g:
testq %rsi, %rsi
jnz .L5
ret
.L5:
addq %rsi, (%rdi)
pushq %rdi
pushq %rsi
subq $1, %rsi
call g
call g
____________________
____________________
addq %rsi, _________
ret
```

(c) Suppose we call \( f(7) \) and immediately before the first instruction of \( f \) is executed, \%rsp contains 0xFFFF0000. Fill in this table to give the contents of registers immediately before the first instruction of \( g \) is executed. Use hex. (Note 0xFFFF0000 is actually too small a 64-bit address to be realistic, but it works fine for an exam problem.)

<table>
<thead>
<tr>
<th></th>
<th>%rdi</th>
<th>%rsi</th>
<th>%rsp</th>
</tr>
</thead>
<tbody>
<tr>
<td>First call to g</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Second call to g</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Third call to g</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fourth call to g</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(d) Does \( g \) “do anything” to save-and-restore any caller-save registers? (yes/no without explanation)

(e) Does \( g \) “do anything” to save-and-restore any callee-save registers? (yes/no without explanation)

(f) Does \( g \) “follow the rules” for the x86-64/Linux calling convention? (yes/no without explanation)
6. (7 points) (Instruction-Set Architecture Design) Suppose we decide to change x86-64 to have 100 registers instead of 16. Give one-word answers to the following questions.

(a) Would this change make it \underline{harder} or \underline{easier} to implement hardware that executes instructions as quickly?

(b) Would this change make it \underline{harder} or \underline{easier} for software to use less stack space?

(c) Would you expect a revised calling convention to have \underline{more} caller-save registers or \underline{fewer} caller-save registers?

(d) Would you expect a revised calling convention to have \underline{more} callee-save registers or \underline{fewer} callee-save registers?

(e) Would it be possible to make this change in a way that existing x86-64 executables could still run without modifying them (\underline{yes} or \underline{no})?
This page intentionally blank. You can use it if you need more room than you have on another page, but please indicate on the other page to look here! Write, “see extra page!”

Assembly Instructions

- `mov a, b`: Copy from a to b.
- `movs a, b`: Copy from a to b with sign extension. Needs two width specifiers.
- `movz a, b`: Copy from a to b with zero extension. Needs two width specifiers.
- `lea a, b`: Compute address and store in b. 
  *Note: the scaling parameter of memory operands can only be 1, 2, 4, or 8.*
- `push src`: Push src onto the stack and decrement stack pointer.
- `pop dst`: Pop from the stack into dst and increment stack pointer.
- `call <func>`: Push return address onto stack and jump to a procedure.
- `ret`: Pop return address and jump there.
- `add a, b`: Add from a to b and store in b (and sets flags).
- `sub a, b`: Subtract a from b (compute b-a) and store in b (and sets flags).
- `imul a, b`: Multiply a and b and store in b (and sets flags).
- `and a, b`: Bitwise AND of a and b, store in b (and sets flags).
- `sar a, b`: Shift value of b right (arithmetic) by a bits, store in b (and sets flags).
- `shr a, b`: Shift value of b right (logical) by a bits, store in b (and sets flags).
- `shl a, b`: Shift value of b left by a bits, store in b (and sets flags).
- `cmp a, b`: Compare b with a (compute b-a and set condition codes based on result).
- `test a, b`: Bitwise AND of a and b and set condition codes based on result.
- `jmp <label>`: Unconditional jump to address.
- `j* <label>`: Conditional jump based on condition codes (*more on next page*).
- `set* a`: Set byte based on condition codes.
