University of Washington — Computer Science & Engineering

CSE 351, Summer 2019 — Final Exam

Friday, August 23rd, 2019

Name: ________________________________

Student ID: ________________________________

Name of student to your left: ________________________________

Name of student to your right: ________________________________

I certify that all work is my own. I had no prior knowledge of exam contents nor will I share the contents with any student in CSE 351 who has not yet taken the exam. Violation of these terms may result in a failing grade.

(Please sign below.)

Signature: ________________________________

Instructions

• You may fill out this page, but do not turn the page until 10:50am.
• This exam is closed-book, except for one handwritten double-sided 8.5×11” note sheet. Calculators, cell phones, smart watches, notes written underneath your sleeves, Google Glasses, Hololens, neural links, and any other futuristic devices are not allowed.
• You have 60 minutes to complete the exam. Please stop promptly at 11:50am.
• The last page of the exam is a reference sheet. Please detach it before turning in your exam.
• Write your Student ID number (not your UW NetID) on the top-right corner of each page.
• We will scan your exams to grade them. Please write clearly and legibly.
• There are 7 questions, totaling 75 points, across 10 pages (including this one).

Advice

• Read the questions thoroughly before answering.
• Write down your thoughts and intermediate steps so that you can get partial credit. But be sure to clearly indicate your final answer.
• Questions are not necessarily in order of difficulty. Skip around or read ahead. Make sure you have a chance to attempt all the questions.
• Relax. You are here to learn 😊.

1. (14 points) A Pretty structured Question

Your instructor decides that his company, WolfBytes™, needs a new website to market their Intel clone CPUs. He's decided to write the website in C and wants to use a linked list of structs, the definition of which is shown below, to store their product information.

```c
struct cpu {
    float clock_speed;
    struct cpu *next;
    short num_cores;
    int cache_size;
    short cache_assoc;
};
```

(a) (5 points) We've come out with a new CPU and want to add to our catalog. Our new CPU has a clock speed of 2.4 GHz. Given a pointer `start` to the beginning of our catalog list, create a new `struct cpu` on the heap, set its clock speed, and add it to the end of the list. You don't need to set the rest of the parameters or #include any libraries.

```c
void add_new_cpu(struct cpu *start) {
    struct cpu *cpu = ________________________________;

    ................................................................................
    ................................................................................
    ................................................................................
    ................................................................................
    ................................................................................
    ................................................................................
}
```

For the following parts, assume x86-64.

(b) (6 points) How much space does an instance of `struct cpu` use? How many bytes are lost to internal and external fragmentation?

<table>
<thead>
<tr>
<th>Total Space</th>
<th>Internal Fragmentation</th>
<th>External Fragmentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>__________ bytes</td>
<td>__________ bytes</td>
<td>__________ bytes</td>
</tr>
</tbody>
</table>

(c) (3 points) By rearranging the elements, we may be able to reduce the size of a `struct cpu`. Give the minimized size in bytes.

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Page 2
2. (18 points) Cache Ya Later!

WolfBytes’s new entry-level CPU, GREYWOLF, uses the following cache parameters:

- A 2-way set-associative cache with 8 total sets and 4 byte cache blocks.
- Write-back, write-allocate, and least-recently-used policies.
- 10-bit wide physical addresses.

(a) (1 point) What is the total size of the cache in bytes?

(b) (3 points) How many bits do we use for the Tag, Index, and Offset?

<table>
<thead>
<tr>
<th>Tag</th>
<th>Index</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(c) (10 points) Now simulate, in order, each of the following 1-byte memory accesses. Fill out the table with the binary representation of the memory address, whether the access resulted in a cache hit or miss, and whether the access resulted in any data being written to memory. Assume that the cache starts cold, but that each access updates the cache. The first entry is completed for you.

<table>
<thead>
<tr>
<th>Access</th>
<th>Binary Address</th>
<th>Cache hit?</th>
<th>Data written to memory?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read 0x023</td>
<td>0b00 0010 0011</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Read 0x028</td>
<td>____________</td>
<td>__________</td>
<td>__________</td>
</tr>
<tr>
<td>Write 0x14B</td>
<td>____________</td>
<td>__________</td>
<td>__________</td>
</tr>
<tr>
<td>Read 0x02A</td>
<td>____________</td>
<td>__________</td>
<td>__________</td>
</tr>
<tr>
<td>Read 0x369</td>
<td>____________</td>
<td>__________</td>
<td>__________</td>
</tr>
</tbody>
</table>

(d) (4 points) Give one benefit and one drawback of using a fully-associative cache as opposed to a set-associative cache.
3. (8 points) If You See a fork In The Road—Take It!

You are given the following snippet of code:

```c
void pillow() {
    int x = 8;
    if (fork()) {
        x++;
        printf("%d ", x);
        if (!fork()) {
            printf("%d ", x - 3);
            return;
        }
    } else {
        x--;
    }
    printf("%d ", x);
}
```

(a) (3 points) Give three possible outputs from the above code.

(b) (2 points) How many total processes are created?

(c) (3 points) What happens to each of the child processes after the parent process terminates? How can the parent prevent this?
4. (14 points) Let’s Get Virtual (Memory)

WolfBytes’s midrange CPU, TIMBERWOLF, uses the following parameters for virtual memory:

- 24-bit virtual addresses, 256 KiB of RAM with 512-byte pages.
- A fully associative 8-entry TLB with LRU replacement.

(a) (4 points) Calculate the following values:

<table>
<thead>
<tr>
<th>Page offset width</th>
<th># of physical pages</th>
<th># of virtual pages</th>
<th>TLBT width</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

One process running on the CPU uses a page-aligned array arr containing 2048 shorts in the code shown below. Assume that the entirety of arr[] starts on disk.

```c
void pandas(short arr[], short s) {
    for (int i = 0; i < 2048; i += 4) {
        arr[i] += s;
    }
}
```

(b) (2 points) What is the stride (in bytes) of memory accesses to arr between each iteration of the loop?

(b) _________________

(c) (3 points) What is the TLB hit rate?

(c) _________________

(d) (3 points) What is the page table hit rate?

(d) _________________

(e) (2 points) We’ve said in lecture that pages are analogous to cache blocks (i.e., they are the unit of data transfer between memory and disk). Why are pages significantly larger than cache blocks?

(e) _________________
5. (11 points) A Nice Hot Cup of Java

WolfBytes has gotten wind of this fancy new language called “Java” and has decided to re-write their website using it. They’ve written two classes to store information about their CPUs:

```java
class CPU {
    float clockSpeed;
    int cacheSize;
    int cacheAssoc;

    int getCores() {
        return 1;
    }
}

class MultiCoreCPU extends CPU {
    int numberOfCores;
    float[] coreSpeeds = new float[16];

    int getCores() {
        return numberOfCores;
    }

    float[] getCoreSpeeds() {
        return coreSpeeds;
    }
}
```

(a) (4 points) The vtable for CPU is shown below. Annotate the diagram with the changes that we would need to make for the vtable of MultiCoreCPU.

You may assume that the alignment for this JVM implementation is the same as C on x86-64, and that fields are stored in memory in the order that they are declared.

(b) (2 points) How much space does an instance of CPU take up?

(b) ______________

(c) (3 points) How much space does an instance of MultiCoreCPU take up?

(c) ______________

(d) (2 points) Give an example of something that is allowed in C, but not in Java, because it would prevent the garbage collector from working properly.
6. (9 points) Don’t You Forget About Me(mory)

Consider the following C code:

```c
int *foo () {
    int **bar = (int **) malloc (sizeof(int) * 4);
    bar ++;
    int *quux = bar [0];
    free (bar);
    return 0;
}
```

(a) (3 points) Assume that, in the code shown above, the call to malloc succeeds and that bar and quux are stored in memory (i.e., not in registers). Fill in the following blanks with “>”, “<”, or “unknown” to compare the values returned by the following expression right before the return statement.

```
&bar __________ &foo
bar _______ &quux
quux __________ &quux
```

(b) (4 points) The code shown above contains two memory-related errors. Describe the two errors, including the line numbers on which they occur.

(c) (2 points) Give a specific advantage of using an explicit free list as opposed to an implicit list when writing a memory allocator.
7. (1 point) I Want Free Points!!
If you still have time left over, draw something cool on this page?

Thank you for a great quarter! Have an awesome fall! 😊
### Assembly Instructions

```assembly
mov a, b          Copy from a to b.
movs a, b         Copy from a to b with sign extension. Needs two width specifiers.
movz a, b         Copy from a to b with zero extension. Needs two width specifiers.
lea a, b          Compute address and store in b.
                   Note: the scaling parameter of memory operands can only be 1, 2, 4, or 8.
push src          Push src onto the stack and decrement stack pointer.
pop dst           Pop from the stack into dst and increment stack pointer.
call <func>       Push return address onto stack and jump to a procedure.
ret                Pop return address and jump there.
add a, b          Add from a to b and store in b (and sets flags).
sub a, b          Subtract a from b (compute b-a) and store in b (and sets flags).
imul a, b         Multiply a and b and store in b (and sets flags).
and a, b          Bitwise AND of a and b, store in b (and sets flags).
sar a, b          Shift value of b right (arithmetic) by a bits, store in b (and sets flags).
shr a, b          Shift value of b right (logical) by a bits, store in b (and sets flags).
shl a, b          Shift value of b left by a bits, store in b (and sets flags).
cmp a, b          Compare b with a (compute b-a and set condition codes based on result).
test a, b         Bitwise AND of a and b and set condition codes based on result.
jmp <label>       Unconditional jump to address.
j* <label>       Conditional jump based on condition codes (more on next page).
set* a            Set byte based on condition codes.
```
### Conditionals

### C Functions

- `void *malloc(size_t size);`: Allocate size bytes from the heap.
- `void *calloc(size_t n, size_t size);`: Allocate n*size bytes and initialize to 0.
- `void free(void *ptr);`: Free the memory space pointed to by ptr.
- `size_t sizeof(type);`: Returns the size of a given type (in bytes).
- `char *gets(char *s);`: Reads a line from stdin into the buffer.
- `pid_t fork();`: Create a new child process (duplicates parent).
- `pid_t wait(int *status);`: Blocks calling process until any child process exits.
- `int execv(char *path, char *argv[]);`: Replace current process image with new image.
