Design of Digital Circuits and Systems

Memory II

Instructor: Justin Hsia

Teaching Assistants:

Colton Harris	Deepti Anoop
Gayathri Vadhyan	Jared Yoder
Lancelot Wathieu	Matthew Hung

Relevant Course Information

- Lab 1 report due tomorrow (4/5)
- Lab 1 demo due by end of 4/12
  - See Lab Demo Slot assignment on Canvas
- Lab 2 report due next Friday (4/12)

- Homework 2 due next Wednesday (4/10)

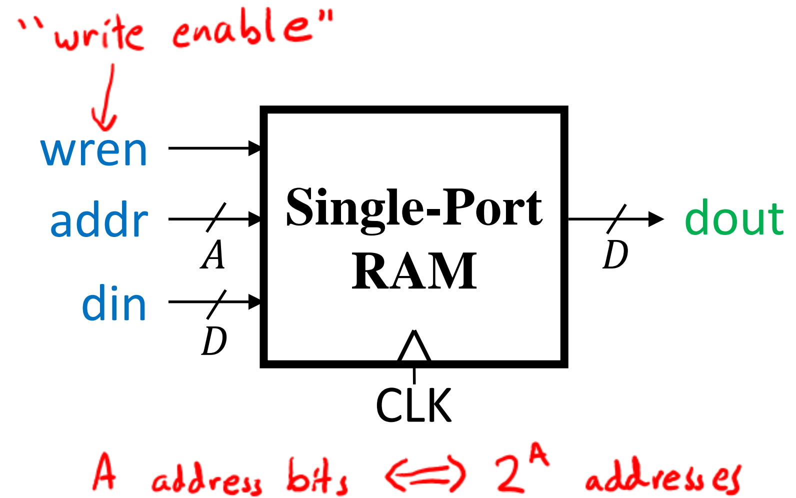
- Use Ed Discussion to ask course questions
  - If sensitive, can email *from a UW-associated email account*
  - Do NOT use Canvas messages

Lab 2 Notes

- Implementing a few **RAM variants** on the DE1-SoC
  - Using both a library catalog and user-specified RAM modules
- Learn how to create and use a **memory initialization file** (*.mif*) to initialize memory on your board
- Feel free to reuse other modules (*e.g.*, input, clock divider, 7-seg, counter) from 271/369
  - Simple modules don't need diagrams or simulations, but they should be shown in the block diagram and mentioned in your report

Synchronous Single-Port RAM (Review)

- Synchronous Inputs:
  - wren (1 = write, 0 = read)
  - addr (A-bit address)
  - din (D-bit data)
- Synchronous Output:
  - dout (D-bit data)



- Implementation hints:
  - Will need an internal RAM array of what size? $2^A \times D$
  - To synchronize, should update on clock triggers always_ff @ (posedge clk)
  - What should dout do when wren = 1? also set to din

Synchronous Single-Port RAM (Review)

```
module RAM_single #(parameter A, D)
                  (clk, wren, addr, din, dout);

   input  logic clk, wren;
   input  logic [A-1:0] addr;
   input  logic [D-1:0] din;
   output logic [D-1:0] dout;

   logic [D-1:0] RAM [0:2**A-1];

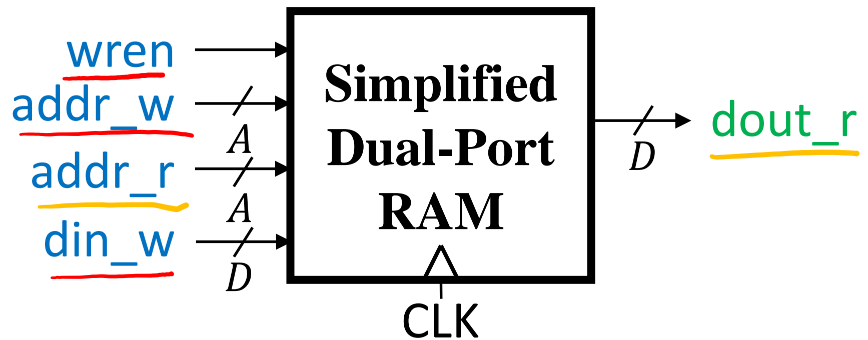
   always_ff @(posedge clk) begin
      if (wren) begin
         RAM[addr] <= din;
         dout <= din;
      end
      else
         dout <= RAM[addr];
   end  // always_ff

endmodule
```

Handwritten annotations:
- On `[0:2**A-1]`: could be either ordering since we aren't loading from a file
- On `if (wren) begin`: // write
- On `dout <= din;`: can't be RAM[addr] because non-blocking assignment
- On `else`: // read

Simplified Synchronous Dual-Port RAM

- 2 ports with 1 dedicated to writing and the other dedicated to reading
- Synchronous Inputs:
  - `wren` (`1` = write, `0` = read)
  - `addr_w` (A-bit address)
  - `addr_r` (A-bit address)
  - `din_w` (D-bit data)
- Synchronous Output:
  - `dout_r` (D-bit data)



- Differences in SystemVerilog?

→ read from addr_r, write to addr_w

→ edge case only if addr_r == addr_w

Simplified Synchronous Dual-Port RAM (SV)

```
module RAM_dual_simple #(parameter A, D)
                (clk, wren, addr_w, addr_r, din_w, dout_r);

   input  logic clk, wren;
   input  logic [A-1:0] addr_w, addr_r;
   input  logic [D-1:0] din_w;
   output logic [D-1:0] dout_r;

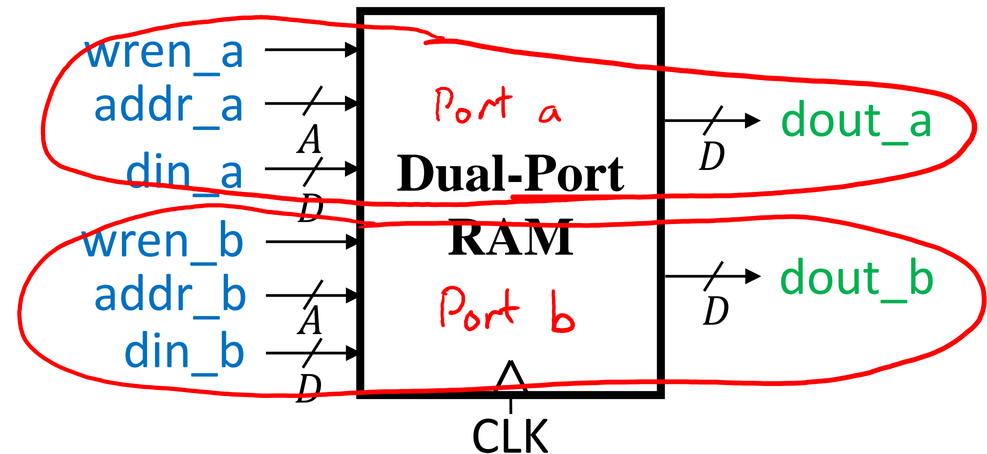
   logic [D-1:0] RAM [0:2**A-1];

   always_ff @(posedge clk) begin
      if (wren) begin
         RAM[addr_w] <= din_w;      // write to addr_w
         dout_r <= (addr_r == addr_w) ? din_w : RAM[addr_r];
      end                           // only a conflict if addr_r == addr_w
      else
         dout_r <= RAM[addr_r];     // read from addr_r
   end  // always_ff

endmodule
```

Synchronous Dual-Port RAM

- The most general configuration – each port can either read or write
- Synchronous Inputs:
  - wren_a and wren_b
  - addr_a and addr_b
  - din_a and din_b
- Synchronous Output:
  - dout_a and dout_b



- Differences in SystemVerilog?

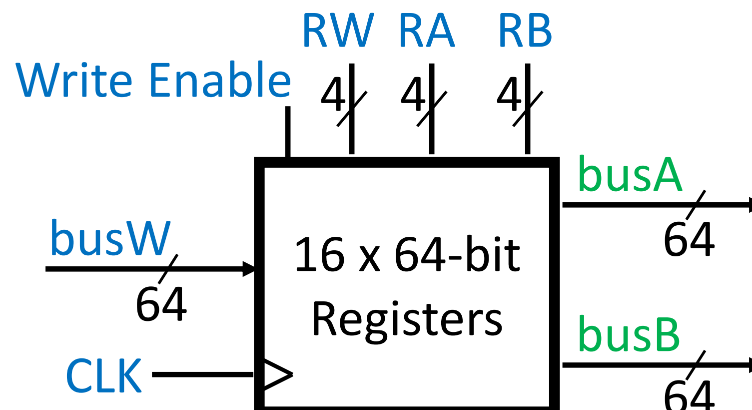
→ two sets of reading & writing connections
→ what if writing to both addr_a == addr_b ?

Memory

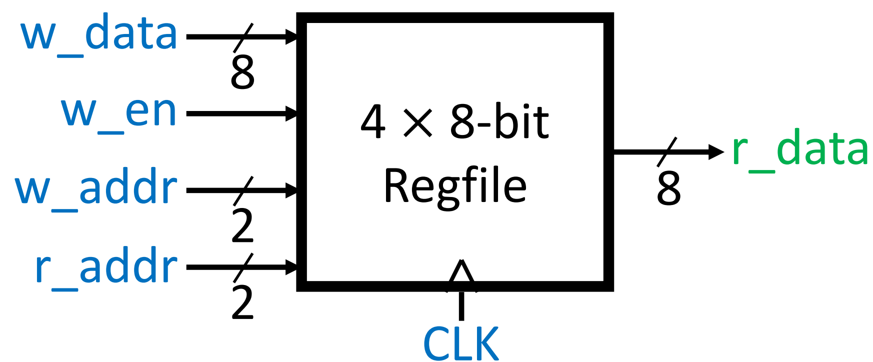
- Several forms of memory are available, which include:
  - ~~Secondary memory (*e.g.*, hard disk, flash drive)~~
  - Read-only memory (ROM)
  - Random-access memory (RAM)
  - Register files
    - Small, fast, fixed-sized memory that hold CPU data state
  - First in, first out (FIFO) buffers

Memory Type #3: Register File

- Register File – a collection of registers
  - 1 input data port – can only write to 1 register at a time
  - 1+ output data ports – can read from 1+ register at a time
  - Address inputs to specify read/write targets
  - Write enable
- Frequently used in CPUs or as fast buffers
- Example:



Simple Register File (4 reg, 1 read port)



controlled registers (with enable)

Reg0 00 D Q en0
Reg1 11 D Q en0
Reg2 22 D Q en0
Reg3 33 D Q en0

w_data 0 1 0 1 0 1 0 1

write logic

demultiplexor

DMX

w_en 1

w_addr 0 0

read logic

multiplexor

MUX

0 0 1 0 0 0 1 0 r_data

r_addr 1 0

Memory Review

- Can think of reg file as a 2-D array of D flip-flops:

- The simple reg file was labeled 4 × 8
  - SystemVerilog array declaration: logic [7:0] reg_array [0:3];
- For a generic reg file with parameters `D_WIDTH` and `A_WIDTH`:
  - Depth: 2^{A_WIDTH}
  - Width: D_WIDTH
  - SystemVerilog array declaration:

```
logic [D_WIDTH-1:0] reg_array [0:2**A_WIDTH-1];
```

Register File with 1 Read Port (SV)

```
module reg_file #(parameter D_WIDTH=8, A_WIDTH=2)
               (clk, w_data, w_en, w_addr, r_addr, r_data);

   input  logic clk, w_en;
   input  logic [A_WIDTH-1:0] w_addr, r_addr;
   input  logic [D_WIDTH-1:0] w_data;
   output logic [D_WIDTH-1:0] r_data;

   // array declaration (registers)
   logic [D_WIDTH-1:0] array_reg [0:2**A_WIDTH-1];        ← registers

   // write operation (synchronous)
   always_ff @(posedge clk)                   } write logic
      if (w_en)
         array_reg[w_addr] <= w_data;

   // read operation (asynchronous)
   assign r_data = array_reg[r_addr];         } read logic

endmodule
```

Where's the Hardware?

```
module reg_file #(parameter D_WIDTH=8, A_WIDTH=2)
               (clk, w_data, w_en, w_addr, r_addr, r_data);

   input  logic clk, w_en;
   input  logic [A_WIDTH-1:0] w_addr, r_addr;
   input  logic [D_WIDTH-1:0] w_data;
   output logic [D_WIDTH-1:0] r_data;

   // array declaration (registers)
   logic [D_WIDTH-1:0] array_reg [0:2**A_WIDTH-1];

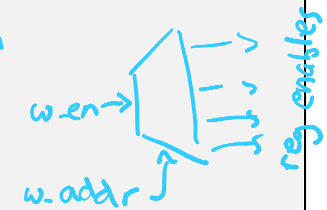
   // write operation (synchronous)
   always_ff @(posedge clk)
      if (w_en)
         array_reg[w_addr] <= w_data;

   // read operation (asynchronous)
   assign r_data = array_reg[r_addr];

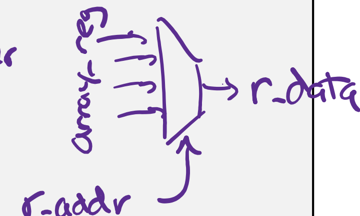
endmodule
```

← registers

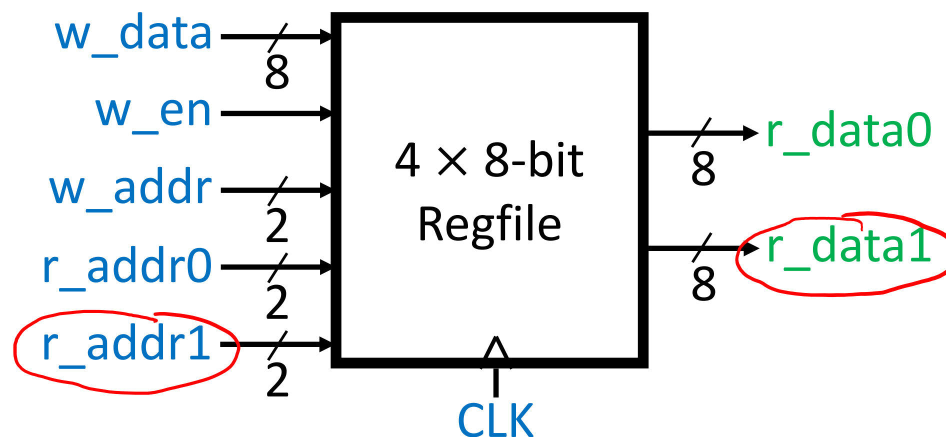
} DEMUX of w_en with w_addr as selector to enable inputs



} MUX with r_addr as selector

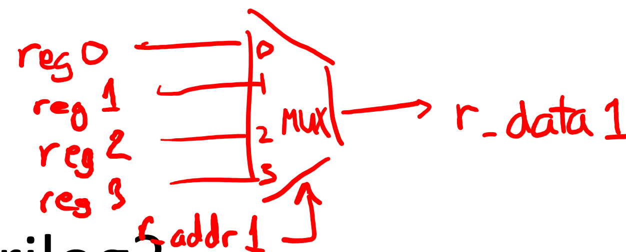


Register File with 2 Read Ports



- What would change in hardware?

add an extra MUX



- What would change in SystemVerilog?

add second assign statement:

```
assign r_data1 = array_reg[r_addr1];
```

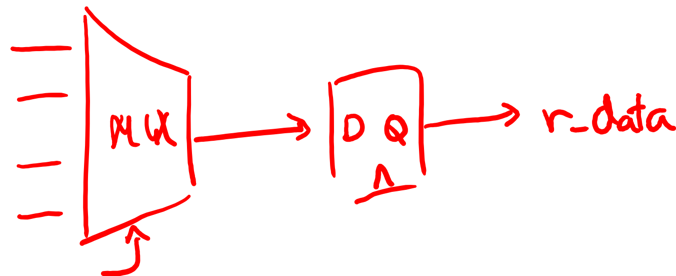
Register File with Synchronous Read

- Back to the 1 read port version, but now we want to make reading *synchronous*:
  - What would change in SystemVerilog?

    move the r_data = array_reg [r_addr]; into the always_ff block, but outside the if (w_en)

  - What would change in hardware?

    add a register after the MUX:



Short Tech Break

Memory Type #4: FIFO Buffer

- **F**irst-**I**n **F**irst-**O**ut (FIFO) Buffer
  - Data storage such that elements that arrived earlier are accessed before elements that arrived later

  - Has a limited capacity, so there is a notion of *fullness* (full, empty)
  - Useful for synchronization, especially in communication (*e.g.*, UART, disk, network)

FIFO Buffer Functionality

- Implementation we will work towards:

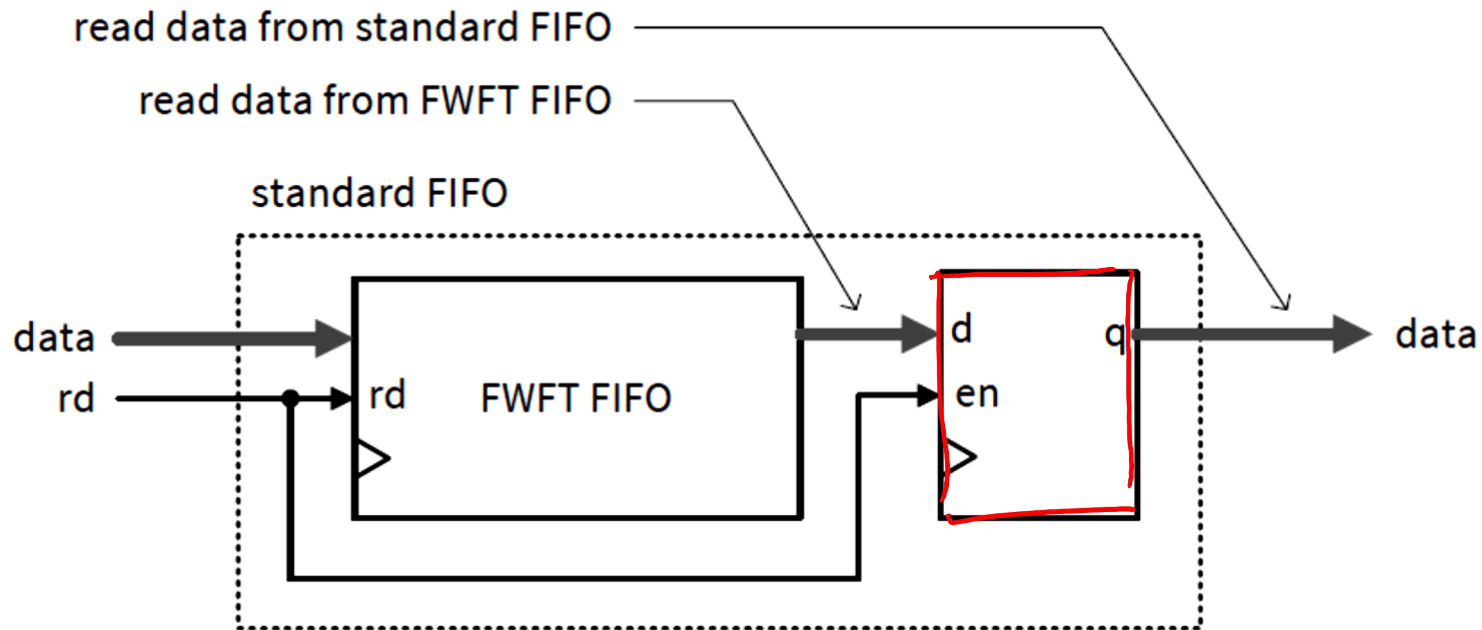
  - `rd` signals to read the next element on `r_data`, `wr` signals to write `w_data` into the buffer
  - Outgoing data is read from the *front/head* of the buffer and incoming data is written to the *back/tail* of the buffer
  - Can be implemented by wrapping a regular memory component with a special *controller*
    - However, the FIFO buffer has no visible notion of address!

FIFO Read Configurations

- First Word Fall Through (FWFT)
  - *Asynchronous* read: front element of buffer always "falls through" and is immediately available on the output bus
    - Including when an element is written to an empty buffer!
  - `rd` therefore acts more like a "remove" signal
- Standard
  - *Synchronous* read: front element of buffer becomes available on next clock cycle after `rd` is asserted
  - `rd` therefore acts more like a "request" signal

FIFO Read Configurations

- Read configuration comparison
  - FWFT can be converted to standard by registering the output:

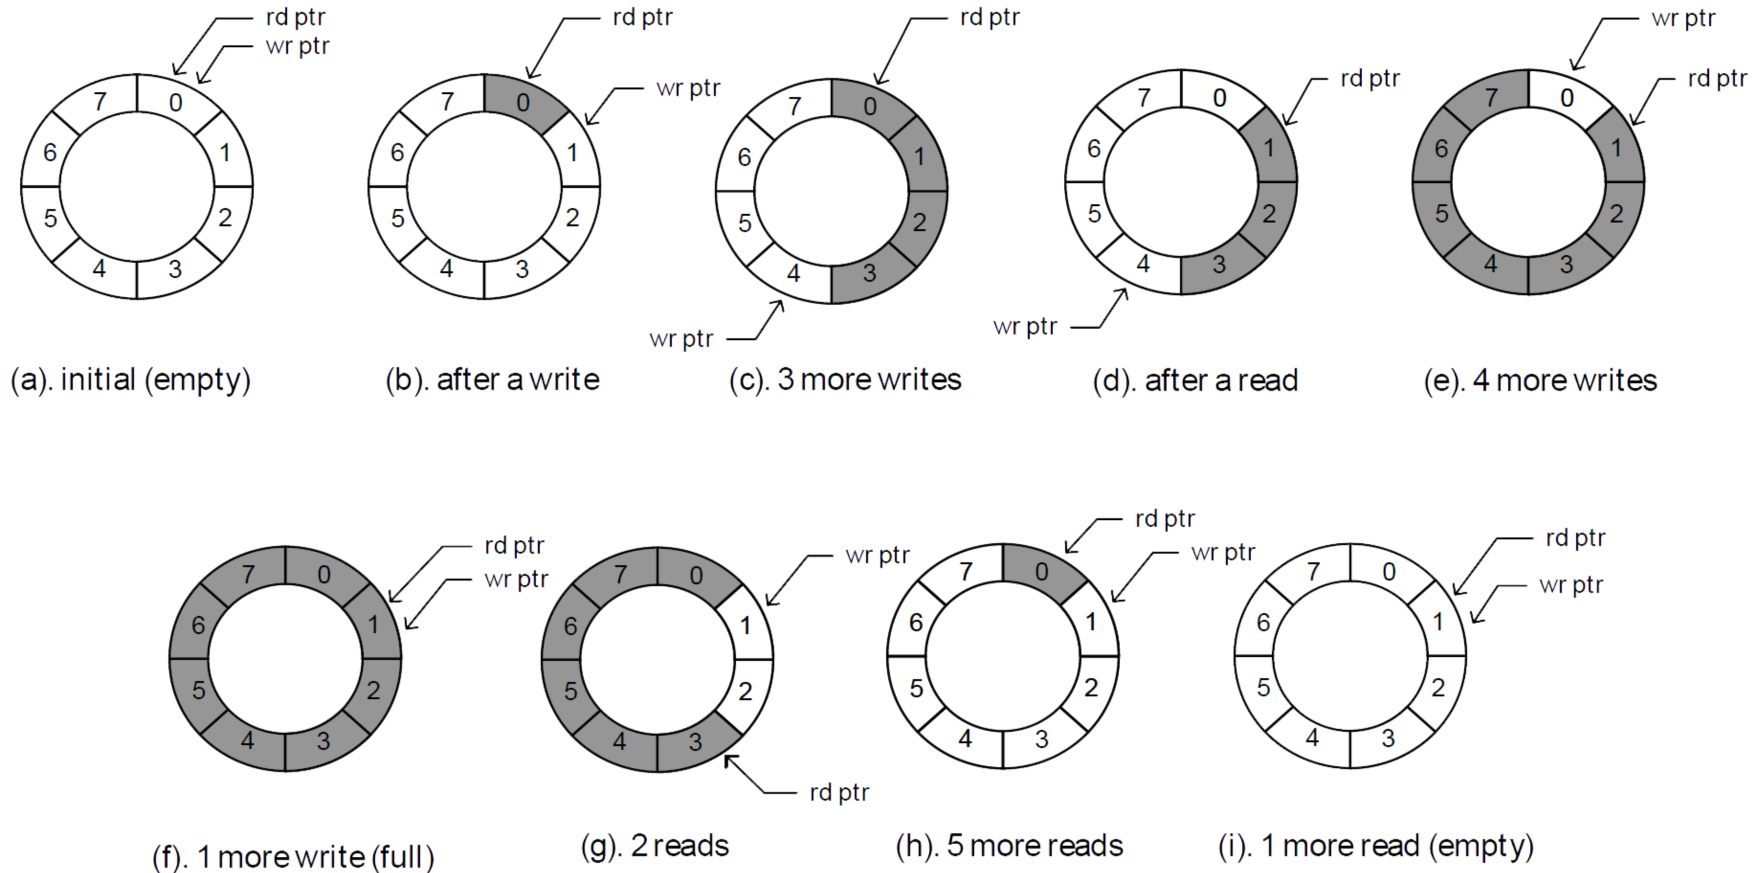


FIFO Implementation

- A FIFO buffer is often implemented as a *circular queue* with two pointers:
  - `rd_ptr` indicates the location of the front/head (*i.e.*, the first valid data) and advances when `rd` is asserted
  - `wr_ptr` indicates the location of the back/tail (*i.e.*, the first empty element) and advances when `wr` is asserted

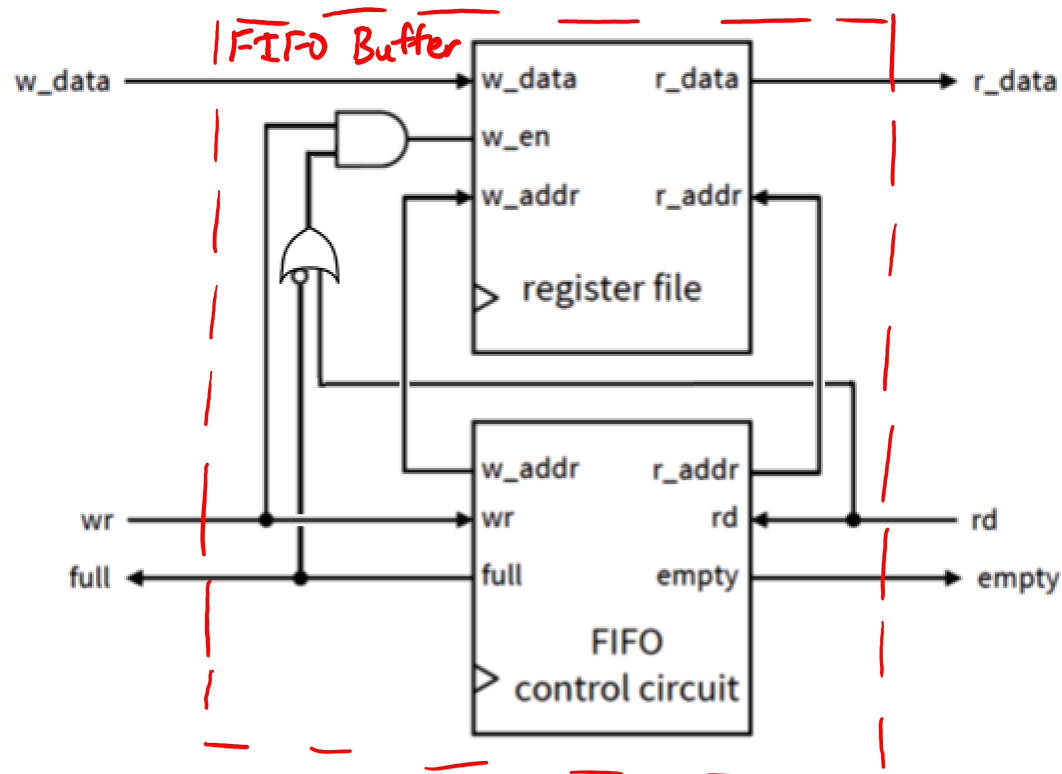
  - `empty` and `full` as buffer fullness status indicators
    - These are tricky because both situations have `rd_ptr == wr_ptr`

Circular Queue Example Operation



Circular Queue Implementation

- A circular queue can be implemented using a RAM module and a *FIFO controller*
  - The controller handles the "arrangement" of the linear memory space into a circular queue



FIFO Controller

- FIFO controller internals:
  - `rd_ptr` and `wr_ptr` are *counters*
  - `empty` and `full` are *flip-flops*
  - Next state logic based on inputs `rd` and `wr`:

rd	wr	rd_ptr	wr_ptr	empty	full
0	0	—	—	—	—
0	1	—	+1	0	1 if new wr_ptr == rd_ptr
1	0	+1	—	1 if new rd_ptr == wr_ptr	0
1	1	+1	+1	—	—

only if ~full (for row rd=0, wr=1)

only if ~empty (for row rd=1, wr=0)

FIFO Controller

- FIFO controller internals:
  - `rd_ptr` and `wr_ptr` are *counters*
  - `empty` and `full` are *flip-flops*
  - Next state logic based on inputs `rd` and `wr`:

    `rw`
    - `00` → no change
    - `11` → advance both `rd_ptr` and `wr_ptr`
      `full` and `empty` don't change
    - `10` → if not `empty`: advance `rd_ptr`,
      set `full` = `0`,
      set `empty` = `1` if `rd_ptr == wr_ptr`
    - `01` → if not `full`: advance `wr_ptr`,
      set `empty` = `0`,
      set `full` = `1` if `rd_ptr == wr_ptr`

FIFO Controller (SV, 1/3)

```
module fifo_ctrl #(parameter A_WIDTH=4)
         (clk, reset, rd, wr, empty, full, w_addr, r_addr);

   input  logic clk, reset, rd, wr;
   output logic empty, full;
   output logic [A_WIDTH-1:0] w_addr, r_addr;

   // next state signal declarations
   logic [A_WIDTH-1:0] rd_ptr, rd_ptr_next;
   logic [A_WIDTH-1:0] wr_ptr, wr_ptr_next;
   logic empty_next, full_next;

   // output assignments
   assign w_addr = wr_ptr;
   assign r_addr = rd_ptr;

   // [continued on next slide...]
```

port declarations

equivalent to declaring ps, ns

FIFO Controller (SV, 2/3)

```
// fifo controller logic
always_ff @(posedge clk) begin
    if (reset)
        begin
            wr_ptr <= 0;
            rd_ptr <= 0;
            full   <= 0;
            empty  <= 1;
        end
    else
        begin
            wr_ptr <= wr_ptr_next;
            rd_ptr <= rd_ptr_next;
            full   <= full_next;
            empty  <= empty_next;
        end

// [continued on next slide...]
```

reset state

equivalent to ps <= ns;

FIFO Controller (SV, 3/3)

```
   // next state logic
   always_comb begin
      // default: keep current values
      rd_ptr_next = rd_ptr;
      wr_ptr_next = wr_ptr;
      empty_next = empty;
      full_next = full;

      // [continued in next box...]
```

implements the next state logic from 3 slides ago

```
      case ({rd, wr})
         2'b11:  // read and write
            begin
               rd_ptr_next = rd_ptr + 1'b1;
               wr_ptr_next = wr_ptr + 1'b1;
            end
         2'b10:  // read
            if (~empty) begin
               rd_ptr_next = rd_ptr + 1'b1;
               if (rd_ptr_next == wr_ptr)
                  empty_next = 1;
               full_next = 0;
            end
         2'b01:  // write
            if (~full) begin
               wr_ptr_next = wr_ptr + 1'b1;
               empty_next = 0;
               if (wr_ptr_next == rd_ptr)
                  full_next = 1;
            end
         2'b00: ; // no change
      endcase
   end  // always_comb

endmodule
```

FIFO Buffer (SV)

```
module fifo #(parameter D_WIDTH=8, A_WIDTH=4)
         (clk, reset, rd, wr, empty, full, w_data, r_data);

   input  logic clk, reset, rd, wr;
   output logic empty, full;
   input  logic [D_WIDTH-1:0] w_data;
   output logic [D_WIDTH-1:0] r_data;

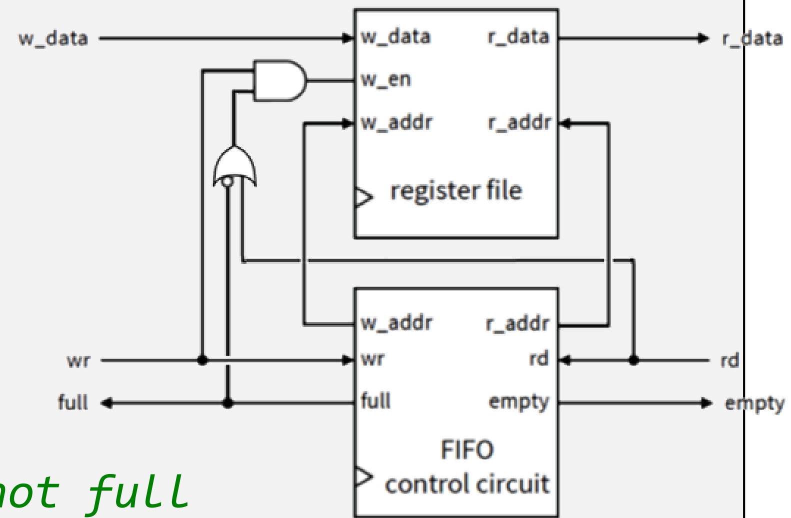
   // signal declarations
   logic [A_WIDTH-1:0] w_addr, r_addr;
   logic w_en;

   // enable write only when FIFO is not full
   assign w_en = wr & (~full | rd);

   // instantiate FIFO controller and register file
   fifo_ctrl #(A_WIDTH) control (.*);
   reg_file #(D_WIDTH, A_WIDTH) mem (.*);

endmodule
```

Writes when wr==1 and rd==1



Memory Controllers

- A *memory controller* is an interface circuit between user logic and the physical memory device
  - Abstracts away details of physical memory device while providing a consistent interface to the user
  - The FIFO controller we just discussed allows a user to interface with the register file we implemented on the FPGA's internal memory module
- Memory controllers are found with all kinds of memory
  - Your DE1-SoC contains memory controllers for SDRAM and DDR3 (and controllers for a bunch of other things like USB, VGA, PS/2, I2C)

DE1-SoC Memory Revisited

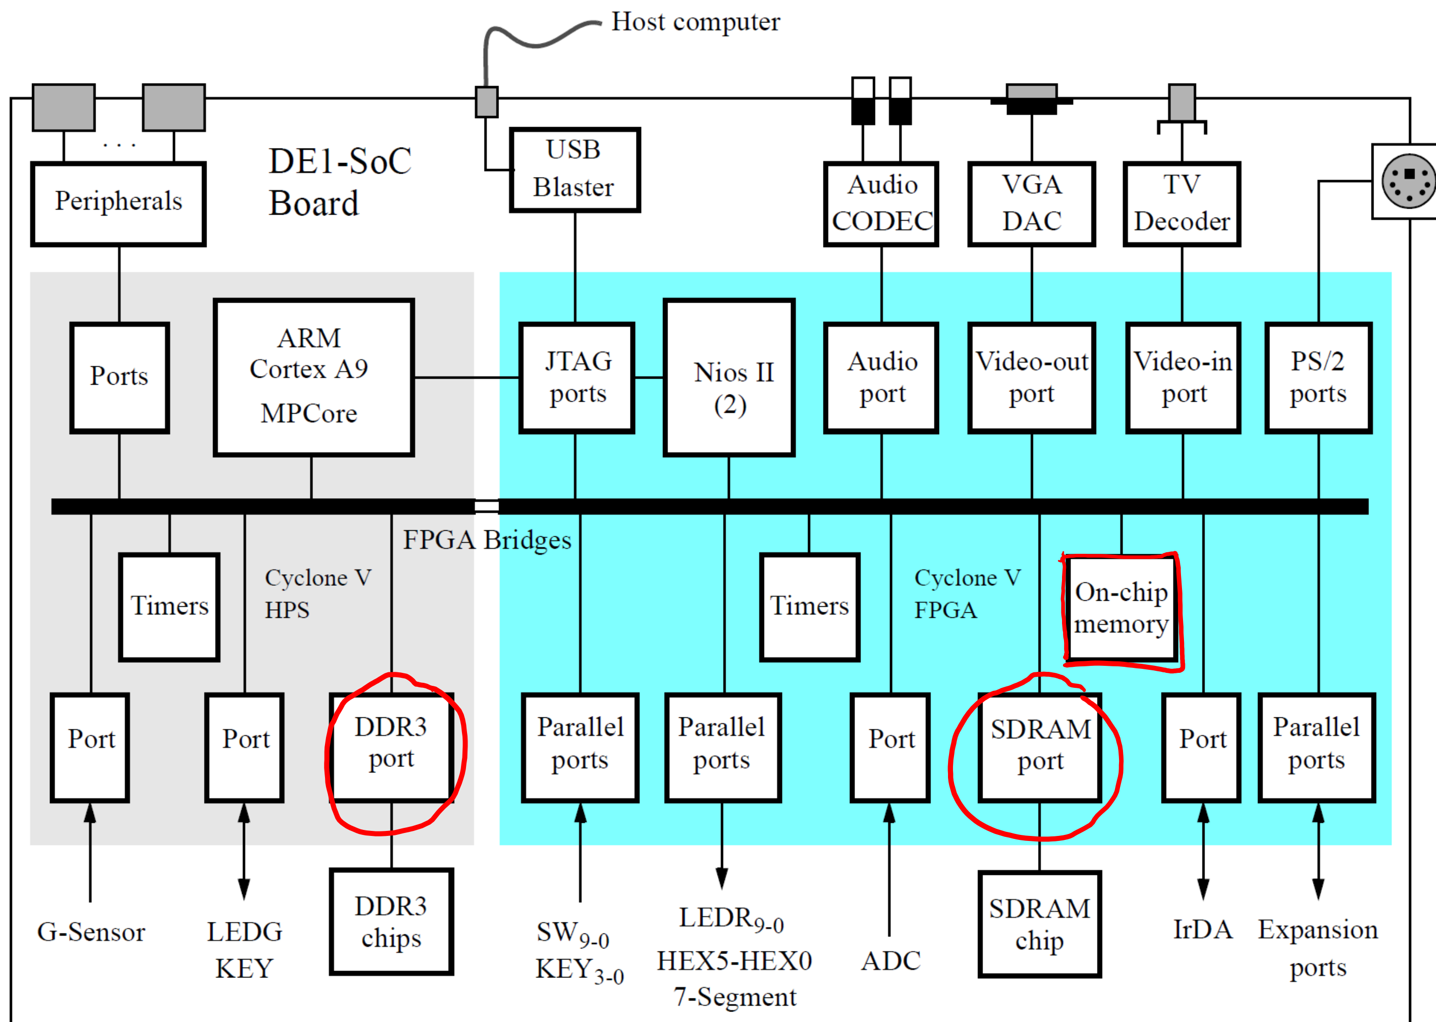


Figure 1. Block diagram of the DE1-SoC Computer.

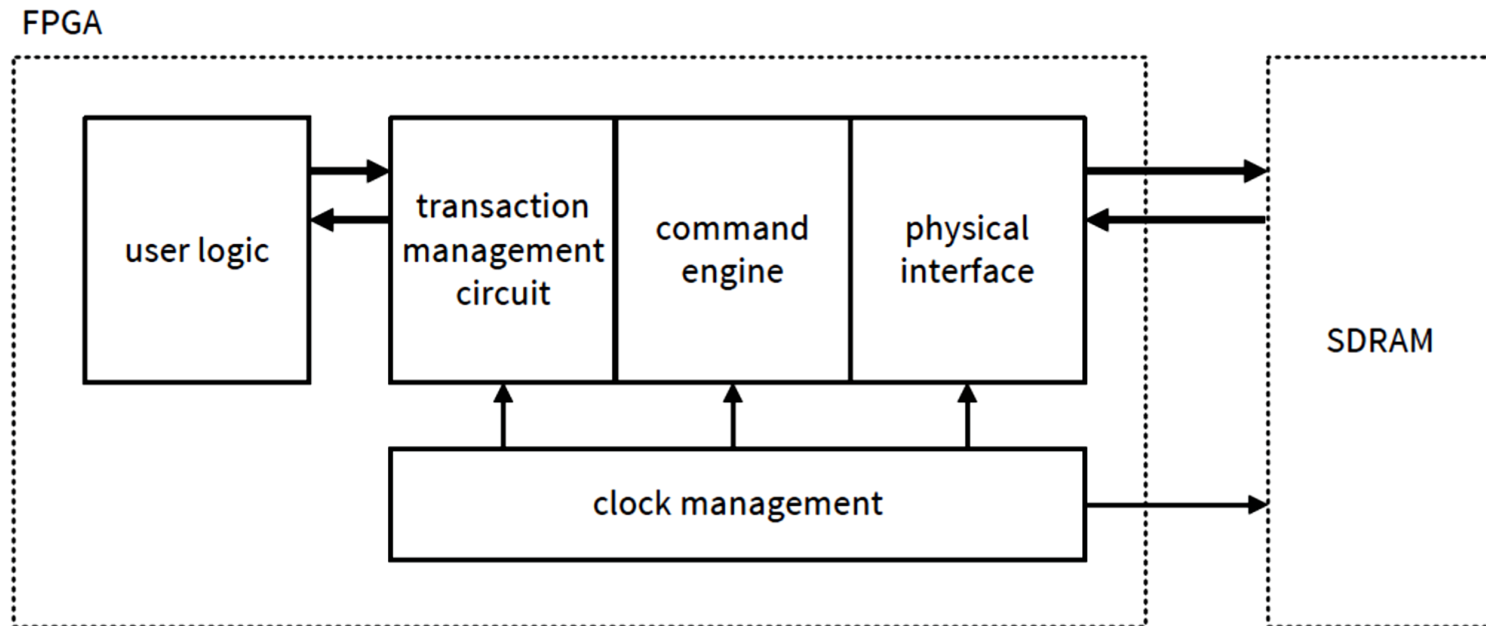
SDRAM Controller



- High-performance controllers are very complex!
  - Design depends on individual FPGA and SDRAM devices
  - Usually constructed with vendor-supplied IP core
