Sort Intro

CSE 373 - Data Structures May 6, 2002

Sorting

- Input
 - > an array A of data records
 - > a key value in each data record
 - > a comparison function which imposes a consistent ordering on the keys
- Output
 - > reorganize the elements of A such that
 - For any i and j, if i < j then $A[i] \le A[j]$

Consistent Ordering

- The comparison function must provided a consistent *ordering* on the set of possible keys
 - You can compare any two keys and get back an indication of a < b, a > b, or a == b
 - > The comparison functions must be consistent
 - If compare(a,b) says a < b, then compare(b,a) must say b > a
 - If compare(a,b) says a=b, then compare(b,a) must say b=a
 - If compare(a,b) says a=b, then equals(a,b) and equals(b,a) must say a=b

Why Sort?

- Allows binary search of an N-element array in O(log N) time
- Allows O(1) time access to kth largest element in the array for any k
- Allows easy detection of any duplicates
- Sorting algorithms are among the most frequently used algorithms in computer science

Space

- How much space does the sorting algorithm require in order to sort the collection of items?
 - > Do you need to copy and temporarily store the set or some subset of the keys and data records?
 - > An algorithm which requires O(1) extra space is known as an *in place* sorting algorithm
 - > Is the algorithm designed for in-memory operation (internal) or does it use disk or tape (external)?

6

Time

- How fast is the algorithm?
 - > The definition of a sorted array A says that for any i < j, A[i] < A[j]
 - > This means that you need to at least check on each element at the very minimum
 - which is O(N)
 - > And you could end up checking each element against every other element
 - which is O(N²)
 - > The big question is: How close to O(N) can you get?

 n^2 n·log₂n 500 700 500 Faster is better! BOD 400 300 200 log₂n

Stability

- Stability: Does it rearrange the order of input data records which have the same key value (duplicates)?
 - > E.g. Phone book sorted by name. Now sort by county is the list still sorted by name within each county?
 - > Extremely important property for databases
 - A stable sorting algorithm is one which does not rearrange the order of duplicate keys

9

Bubble Sort

- "Bubble" elements to to their proper place in the array by comparing elements i and i+1, and swapping if A[i] > A[i+1]
 - > Bubble every element towards its correct position
 - last position has the largest element
 - then bubble every element except the last one towards its correct position
 - then repeat until done or until the end of the quarter
 - whichever comes first ...

10

Bubblesort

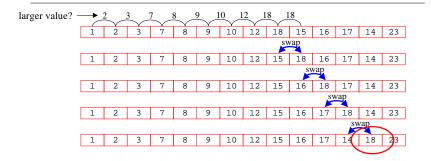

```
/* Bubble sort for integers */
#define SWAP(a,b) { int t; t=a; a=b; b=t; }
void bubble( int A[], int n ) {
  int i, j;
  for(i=0;i<n;i++) { /* n passes thru the array */
    /* From start to the end of unsorted part */
    for(j=1;j<(n-i);j++) {
        /* If adjacent items out of order, swap */
        if( A[j-1] > A[j] ) SWAP(A[j-1],A[j]); }
}
```

Put the largest element in its place

11

Put 2nd largest element in its place

Two elements done, only n-2 more to go ...

15

Bubble Sort: Just Say No

- "Bubble" elements to to their proper place in the array by comparing elements i and i+1, and swapping if A[i] > A[i+1]
- We bubblize for i=0 to n-1 (ie, n times)
- Each bubblization is a loop that makes n-i-1 comparisons
- This is $O(n^2)$

14

Insertion Sort

- What if first *k* elements of array are already sorted?
 - > <u>4, 7, 12, 5, 19, 16</u>
- We can shift the tail of the sorted elements list down and then *insert* next element into proper position and we get k+1 sorted elements

```
> <u>4, 5, 7, 12,</u> 19, 16
```

Insertion Sort

- Is Insertion sort in place? Stable? Running time = ?
- Do you recognize this sort?
 - > This is what we used for percolating binary heap elements.

Insertion Sort Characteristics

- In place and Stable
 - > One extra location for Tmp
- Running time
 - \rightarrow Worst case is $O(N^2)$
 - reverse order input
 - must copy every element every time
 - \rightarrow Best case is $\Omega(N)$
 - in-order input
 - copy down stops with first comparison every time

17

19

Inversions

- An *inversion* is a pair of elements in wrong order
 - $\rightarrow i < j \text{ but } A[i] > A[j]$
- By definition, a sorted array has no inversions
- So you can think of sorting as the process of removing inversions in the order of the elements

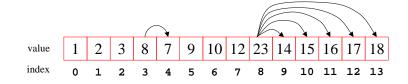

6-May-02

CSE 373 - Data Structures - 13 - Sort Intro

18

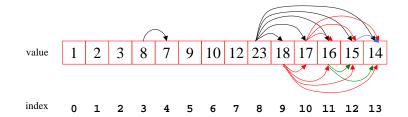

Inversions

 A single value out of place can cause several inversions

Reverse order

• All values out of place (reverse order) causes numerous inversions

Inversions

- Our simple sorting algorithms so far swap adjacent elements (explicitly or implicitly) and remove just 1 inversion at a time
 - > Their running time is proportional to number of inversions in array
- Given N distinct keys, the maximum possible number of inversions is

$$(n-1)+(n-2)+...+1=\sum_{i=1}^{n-1}i=\frac{(n-1)(n)}{2}$$

6-May-02

CSE 373 - Data Structures - 13 - Sort Intro

21

Inversions and Adjacent Swap Sorts

- "Average" list will contain half the max number of inversions = $\frac{(n-1)(n)}{4}$
 - > So the average running time of Insertion sort is $\Theta(N^2)$
- Any sorting algorithm that only swaps adjacent elements requires $\Omega(N^2)$ time because each swap removes only one inversion
