# Data Structures & Algorithms

## Lecture 16

## Disjoint Sets

# Brief Midterm Review

- Problem 1: Heaps
- Problem 2: Hashing
- Problem 3: Sorting
  - Many subquestions

# Equivalence Relations

Relation  $R$  :

- For every pair of elements  $(a, b)$  in a set  $S$ , a  $R b$  is either true or false.
- If a  $R b$  is true, then a *is related* to  $b$ .

An equivalence relation satisfies:

1. (Reflexive)  $a R a$
2. (Symmetric)  $a R b$  iff  $b R a$
3. (Transitive)  $a R b$  and  $b R c$  implies  $a R c$

# A new question

- Which of these things are similar?  
{ grapes, blackberries, plums, apples,  
oranges, peaches, raspberries, lemons }
- If limes are added to this fruit salad, and are similar to oranges, then are they similar to grapes?
- How do you answer these questions efficiently?

# Equivalence Classes

- Given a set of things...  
{ grapes, blackberries, plums, apples, oranges, peaches, raspberries, lemons, bananas }
- ...define the equivalence relation  
All citrus fruit is related, all berries, all stone fruits, and THAT'S IT.
- ...partition them into related subsets  
{ grapes }, { blackberries, raspberries }, { oranges, lemons },  
{ plums, peaches }, { apples }, { bananas }

Everything in an equivalence class is related to each other.

# Determining equivalence classes

- Idea: give every equivalence class a name
  - { oranges, limes, lemons } = “like-ORANGES”
  - { peaches, plums } = “like-PEACHES”
  - Etc.
- To answer if two fruits are related:
  - FIND the name of one fruit’s e.c.
  - FIND the name of the other fruit’s e.c.
  - Are they the same name?

# Building Equivalence Classes

- Start with **disjoint**, singleton sets:
  - { apples }, { bananas }, { peaches }, ...
- As you gain information about the relation, **UNION** sets that are now related:
  - { peaches, plums }, { apples }, { bananas }, ...
- E.g. if peaches R limes, then we get
  - { peaches, plums, limes, oranges, lemons }

# Disjoint Union - Find

- Maintain a set of pairwise disjoint sets.
  - $\{3,5,7\}$  ,  $\{4,2,8\}$ ,  $\{9\}$ ,  $\{1,6\}$
- Each set has a unique name, one of its members
  - $\{3,\underline{5},7\}$  ,  $\{4,2,\underline{8}\}$ ,  $\{\underline{9}\}$ ,  $\{\underline{1},6\}$

# Union

- Union(x,y) – take the union of two sets named x and y
  - {3,5,7} , {4,2,8}, {9}, {1,6}
  - Union(5,1)  
{3,5,7,1,6}, {4,2,8}, {9},

# Find

- Find(x) – return the name of the set containing x.
  - {3,5,7,1,6}, {4,2,8}, {9},
  - Find(1) = 5
  - Find(4) = 8

# Example

Find(8) = 7

Find(14) = 20

Union(7,20)

# Cute Application

- Build a random maze by erasing edges.

# Cute Application

- Pick Start and End

# Cute Application

- Repeatedly pick random edges to delete.

# Desired Properties

- None of the boundary is deleted
- Every cell is reachable from every other cell.
- There are no cycles – no cell can reach itself by a path unless it retraces some part of the path.

# A Cycle

# A Good Solution

# Number the Cells

We have disjoint sets  $S = \{ \{1\}, \{2\}, \{3\}, \{4\}, \dots, \{36\} \}$   
each cell is unto itself.

We have all possible edges  $E = \{ (1,2), (1,7), (2,8), (2,3), \dots \}$   
60 edges total.

Start	1	2	3	4	5	6	
	7	8	9	10	11	12	
	13	14	15	16	17	18	
	19	20	21	22	23	24	
	25	26	27	28	29	30	
	31	32	33	34	35	36	End

# Basic Algorithm

- $S$  = set of sets of connected cells
- $E$  = set of edges
- Maze = set of maze edges initially empty

```
While there is more than one set in  $S$ 
  pick a random edge  $(x,y)$  and remove from  $E$ 
   $u := \text{Find}(x)$ ;
   $v := \text{Find}(y)$ ;
  if  $u \neq v$  then
    Union( $u,v$ )
  else
    add  $(x,y)$  to Maze
All remaining members of  $E$  together with Maze form the maze
```

# Example Step

Pick (8,14)

Start	1	2	3	4	5	6	
	7	8	9	10	11	12	
	13	14	15	16	17	18

# Example at the End

S

{1,2,3,4,5,6,7,... 36}

— E  
— Maze

# Implementing the DS ADT

- $n$  elements,  
Total Cost of:  $m$  finds,  $\leq n-1$  unions
- Target complexity:  $O(m+n)$   
*i.e.*  $O(1)$  amortized
- $O(1)$  worst-case for find as well as union would be great, but...  
*Known result:* find and union *cannot* both be done in worst-case  $O(1)$  time

# Implementing the DS ADT

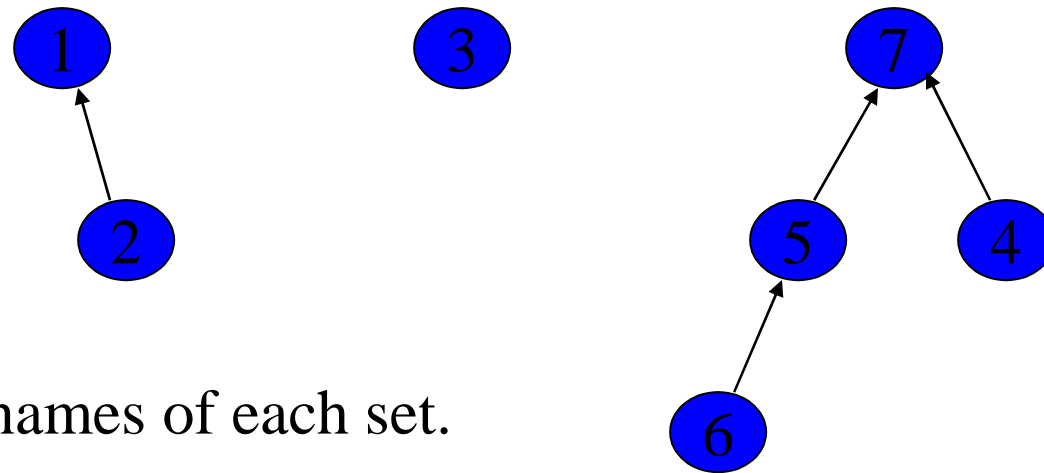

- Observation: *trees* let us find many elements given one root...
- Idea: if we *reverse* the pointers (make them point up from child to parent), we can find a single root from many elements...
- Idea: Use one tree for each equivalence class. The name of the class is the tree root.

# Up-Tree for DU/F

Initial state

Intermediate state

Roots are the names of each set.

# Find Operation

- Find(x) follow x to the root and return the root

# Union Operation

- Union( $i,j$ ) - assuming  $i$  and  $j$  roots, point  $i$  to  $j$ .

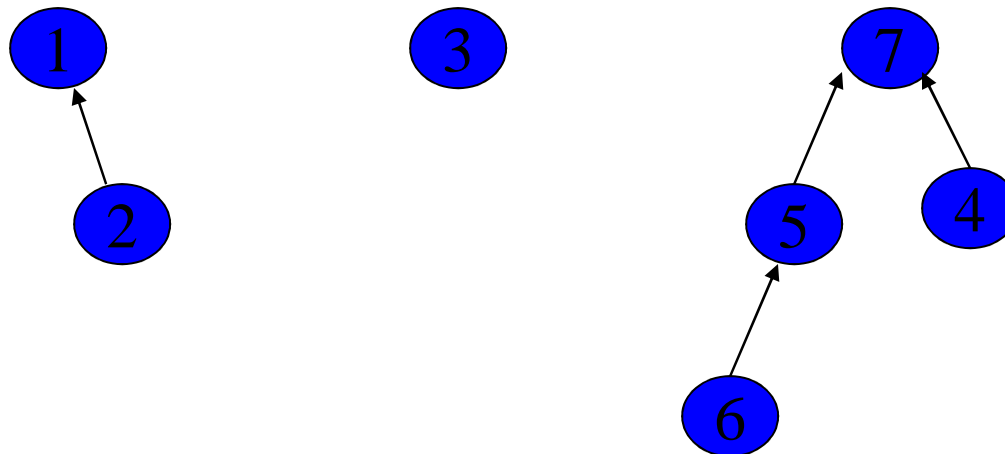

# Simple Implementation

- Array of indices

	1	2	3	4	5	6	7
up	0	1	0	7	7	5	0

$Up[x] = 0$  means  
x is a root.

# Union

```
Union(up[] : integer array, x,y : integer) : {  
  //precondition: x and y are roots//  
  Up[x] := y  
}
```

Constant Time!

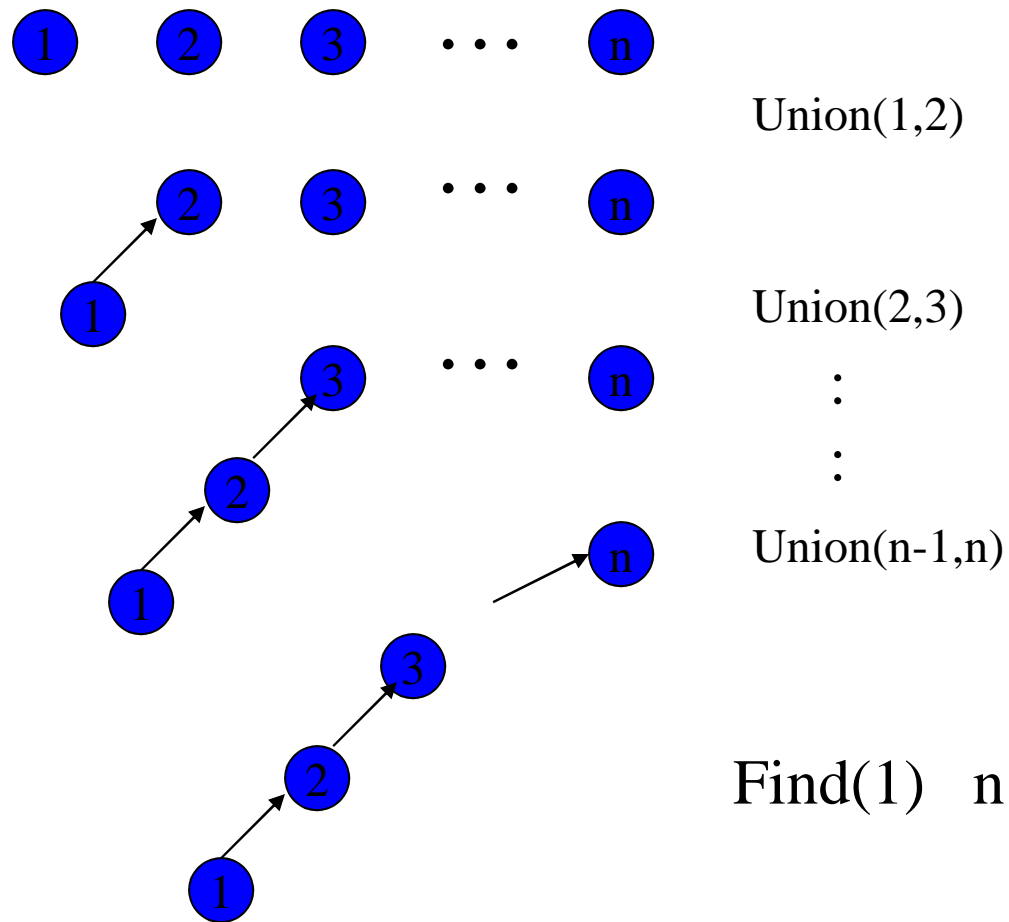

# Exercise

- Design Find operator
  - Recursive version
  - Iterative version

```
Find(up[] : integer array, x : integer) : integer {  
  //precondition: x is in the range 1 to size//  
  ???  
}
```

# A Bad Case

# Now this doesn't look good 😞

Can we do better? *Yes!*

1. Improve **union** so that *find* only takes  $\Theta(\log n)$ 
  - Union-by-size
  - Reduces complexity to  $\Theta(m \log n + n)$
2. Improve **find** so that it becomes even better!
  - Path compression
  - Reduces complexity to almost  $\Theta(m + n)$

# Weighted Union

- Weighted Union
  - Always point the smaller tree to the root of the larger tree

# Example Again

Union(1,2)

Union(2,3)

:  
:

Union(n-1,n)

Find(1) constant time
