Priority Queues: Binary Min Heaps

CSE 373

Data Structures and Algorithms

10/15/2010

Today's Outline

- Announcements
 - Midterm #1, Friday Oct 22.
 - Assignment #3 coming soon.
- · Today's Topics:
 - Dictionary
 - Balanced Binary Search Trees (AVL Trees)
 - Priority Queues
 - Binary Min Heap

10/15/2010

10 2

Priority Queue ADT

1. PQueue data: collection of data with priority

2. PQueue operations

- insert
- deleteMin

(also: create, destroy, is_empty)

3. PQueue property: for two elements in the queue, *x* and *y*, if *x* has a **lower** priority value than *y*, *x* will be deleted before *y*

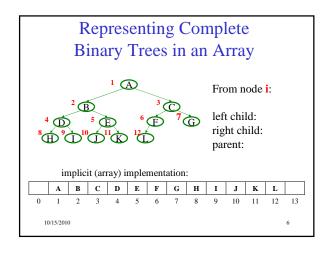

10/15/2010

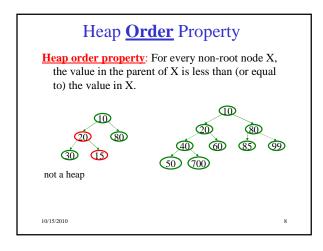

Applications of the Priority Q

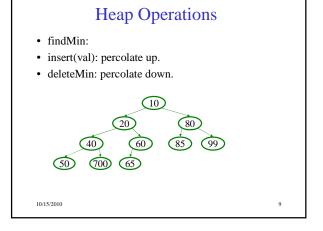

- Select print jobs in order of decreasing length
- Forward packets on network routers in order of urgency
- Select most frequent symbols for compression
- Sort numbers, picking minimum first
- · Anything greedy

10/15/2010 4

Implementations of Priority Queue ADT		
	insert	deleteMin
Unsorted list (Array)		
Unsorted list (Linked-List)		
Sorted list (Array)		
Sorted list (Linked-List)		
Binary Search Tree (BST)		
10/15/2010		5

Heap – Insert(val)

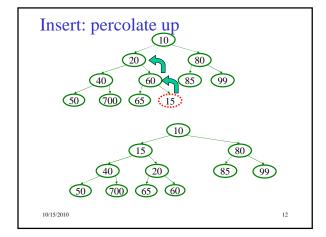

Basic Idea:

- 1. Put val at "next" leaf position
- 2. Repeatedly exchange node with its parent if

10/15/2010

10

Insert pseudo Code (optimized) void insert(Object o) { int percolateUp(int hole, Object val) { while (hole > 1 && assert(!isFull()); size++; val < Heap[hole/2]) Heap[hole] = Heap[hole/2];</pre> newPos = percolateUp(size,o); Heap[newPos] = o; runtime: (Java code in book) 10/15/2010 11

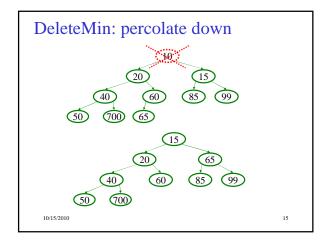

Heap – Deletemin

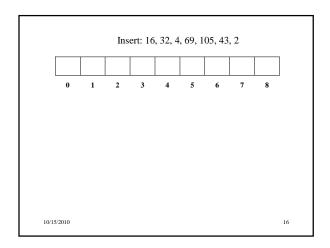

Basic Idea:

- Remove root (that is always the min!)
- Put "last" leaf node at root
- Find smallest child of node
- Swap node with its smallest child if needed.
- 5. Repeat steps 3 & 4 until no swaps needed.

10/15/2010 13

```
DeleteMin pseudo Code (Optimized)
                               int percolateDown(int hole,
 Object deleteMin() {
                               while (2*hole <= size) {
   assert(!isEmpty());
                                    left = 2*hole;
right = left + 1;
if (right ≤ size &&
   returnVal = Heap[1];
   size--;
   newPos =
                                        Heap[right] < Heap[left])</pre>
                                      target = right;
     percolateDown(1,
                                    else
  target = left;
         Heap[size+1]);
   Heap[newPos] =
                                    if (Heap[target] < val) {
  Heap[hole] = Heap[target];</pre>
     Heap[size + 1];
   return returnVal;
                                      hole = target;
runtime:
                                      break;
                                  return hole;
         (Java code in book)
     10/15/2010
                                                                   14
```

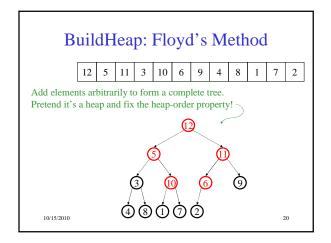

Other Priority Queue Operations • decreaseKey - given a pointer to an object in the queue, reduce its priority value Solution: change priority and • increaseKey - given a pointer to an object in the queue, increase its priority value Solution: change priority and Solution: change priority and Why do we need a pointer? Why not simply data value?

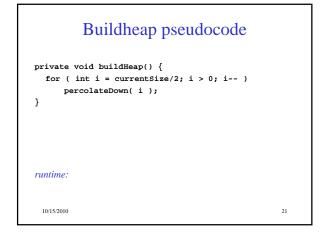

Other Heap Operations decreaseKey(objPtr, amount): raise the priority of a object, percolate up increaseKey(objPtr, amount): lower the priority of a object, percolate down remove(objPtr): remove a object, move to top, them delete. 1) decreaseKey(objPtr, ∞) 2) deleteMin() Worst case Running time for all of these: FindMax? ExpandHeap – when heap fills, copy into new space.

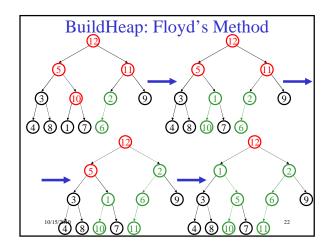

Binary Min Heaps (summary)

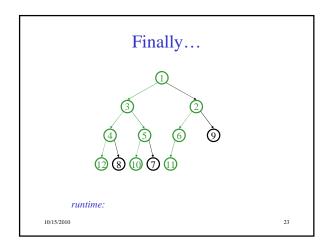

- insert: percolate up. $\Theta(\log N)$ time.
- deleteMin: percolate down. $\Theta(\log N)$ time.
- Build Heap?

10/15/2010 19

Facts about Binary Min Heaps

Observations:

- finding a child/parent index is a multiply/divide by two
- operations jump widely through the heap
- each percolate step looks at only two new nodes
- inserts are at least as common as deleteMins

Realities

- division/multiplication by powers of two are equally fast
- looking at only two new pieces of data: bad for cache!
- with huge data sets, disk accesses dominate
