

CSE373: Data Structures & Algorithms

Lecture 18: Dijkstra's Algorithm

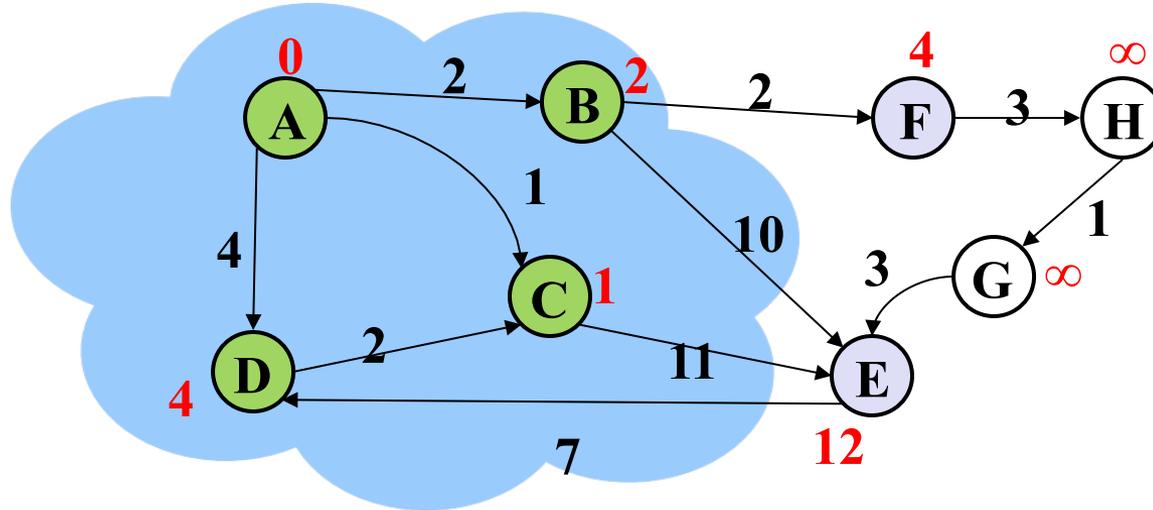

Nicki Dell

Spring 2014

Announcements

- Homework 3 grades out today
- Homework 4 due Wednesday 11pm
- Midterm grades and feedback on Wednesday
- TA sessions
 - Tuesday: help with homework 4
 - Thursday: Dijkstra's algorithm (homework 5!)

Dijkstra's Algorithm: Lowest cost paths

- Initially, start node has cost 0 and all other nodes have cost ∞
- At each step:
 - Pick closest unknown vertex v
 - Add it to the “cloud” of known vertices
 - Update distances for nodes with edges from v
- That's it!

The Algorithm

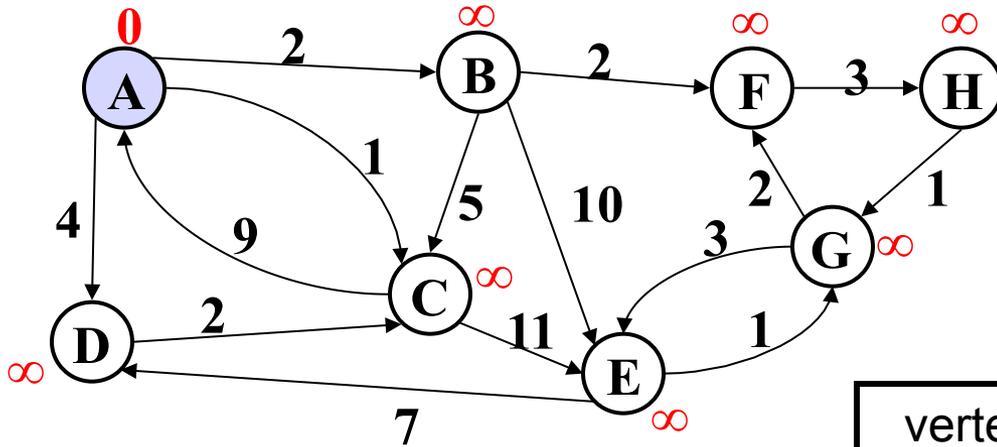

1. For each node v , set $v.cost = \infty$ and $v.known = false$
2. Set $source.cost = 0$
3. While there are unknown nodes in the graph
 - a) Select the unknown node v with lowest cost
 - b) Mark v as known
 - c) For each edge (v, u) with weight w ,

```
    c1 = v.cost + w // cost of best path through v to u
    c2 = u.cost // cost of best path to u previously known
    if (c1 < c2) { // if the path through v is better
        u.cost = c1
        u.path = v // for computing actual paths
    }
```

Features

- When a vertex is marked known, the cost of the shortest path to that node is known
 - The path is also known by following back-pointers
- All the “known” vertices have the correct shortest path
 - True initially: shortest path to start node has cost 0
 - If it stays true every time we mark a node “known”, then by induction this holds and eventually everything is “known”
- While a vertex is still not known, another shorter path to it **might** still be found

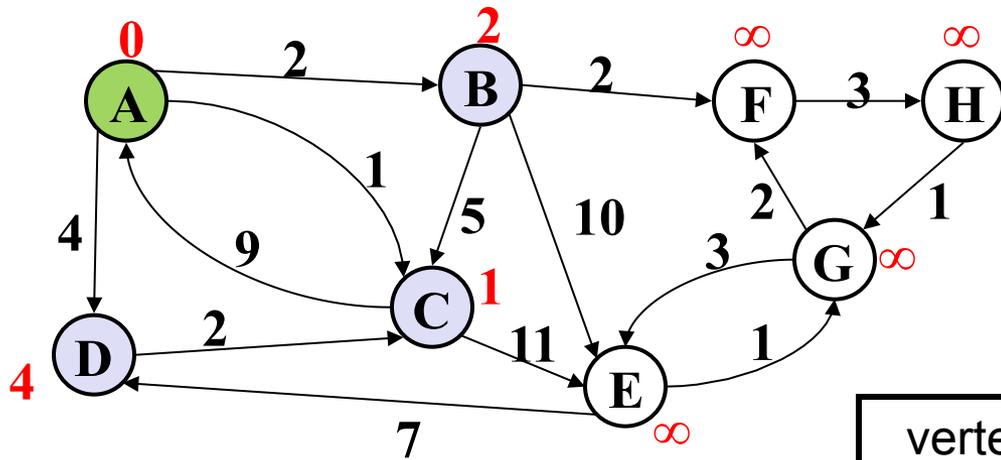

Example #1

vertex	known?	cost	path
A		0	
B		??	
C		??	
D		??	
E		??	
F		??	
G		??	
H		??	

Order Added to Known Set:

Example #1

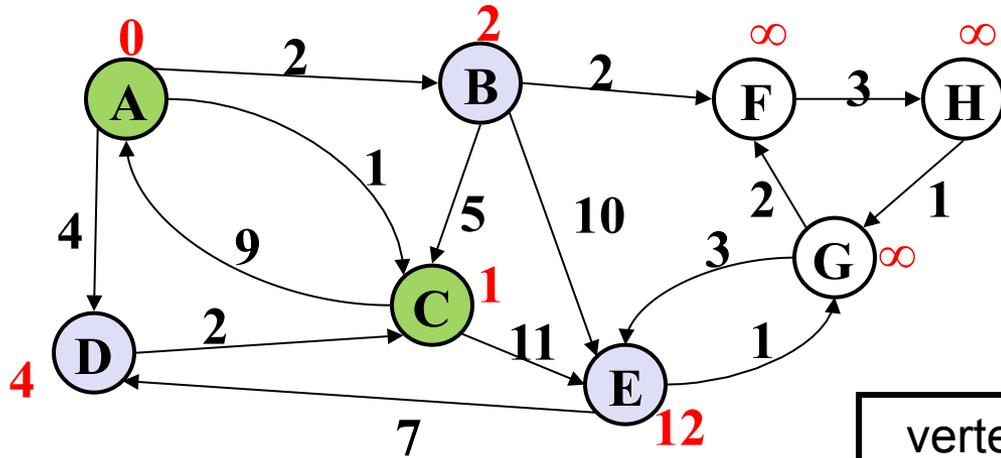

vertex	known?	cost	path
A	Y	0	
B		≤ 2	A
C		≤ 1	A
D		≤ 4	A
E		??	
F		??	
G		??	
H		??	

Order Added to Known Set:

A

Example #1

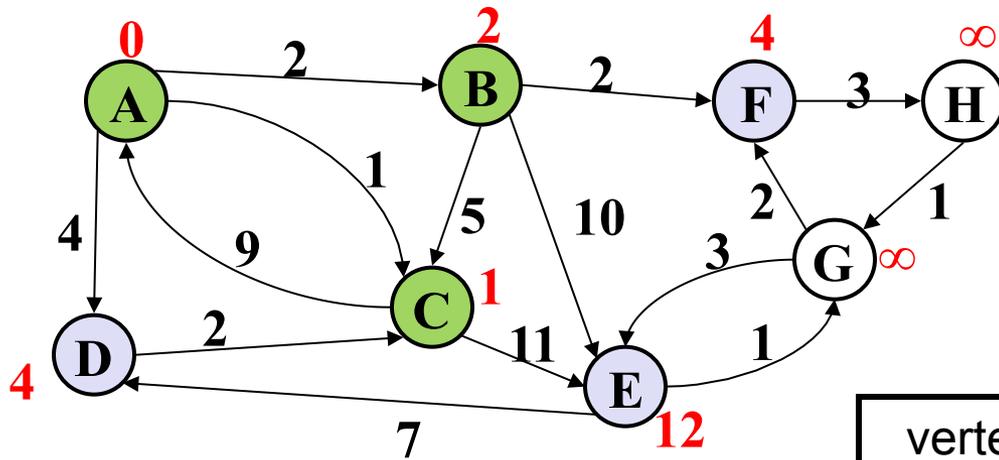

vertex	known?	cost	path
A	Y	0	
B		≤ 2	A
C	Y	1	A
D		≤ 4	A
E		≤ 12	C
F		??	
G		??	
H		??	

Order Added to Known Set:

A, C

Example #1

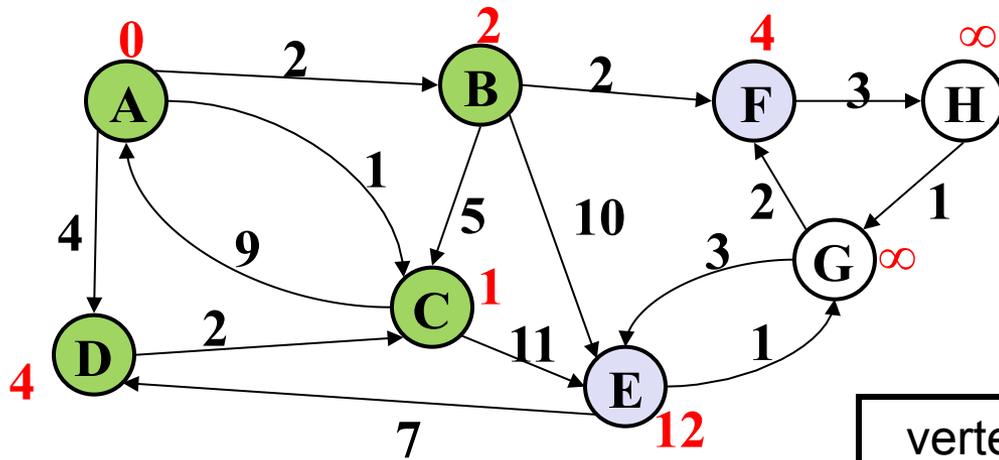

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D		≤ 4	A
E		≤ 12	C
F		≤ 4	B
G		??	
H		??	

Order Added to Known Set:

A, C, B

Example #1

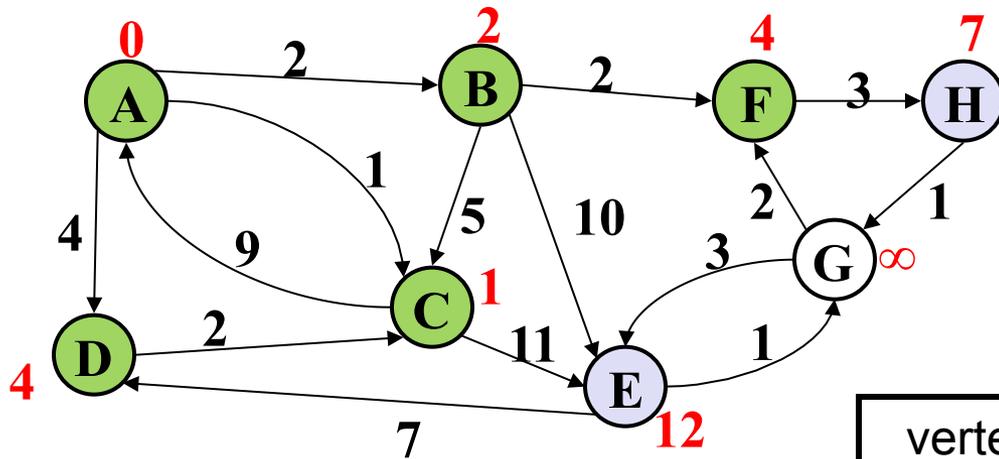

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E		≤ 12	C
F		≤ 4	B
G		??	
H		??	

Order Added to Known Set:

A, C, B, D

Example #1

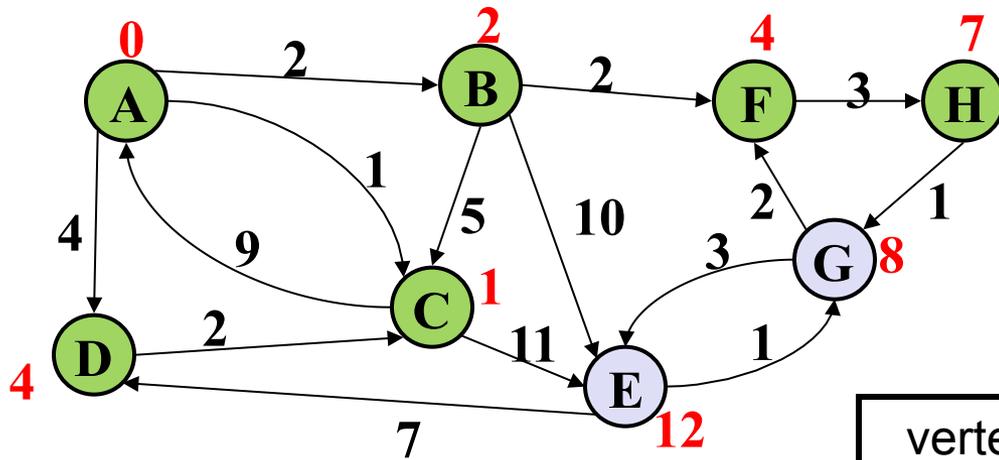

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E		≤ 12	C
F	Y	4	B
G		??	
H		≤ 7	F

Order Added to Known Set:

A, C, B, D, F

Example #1

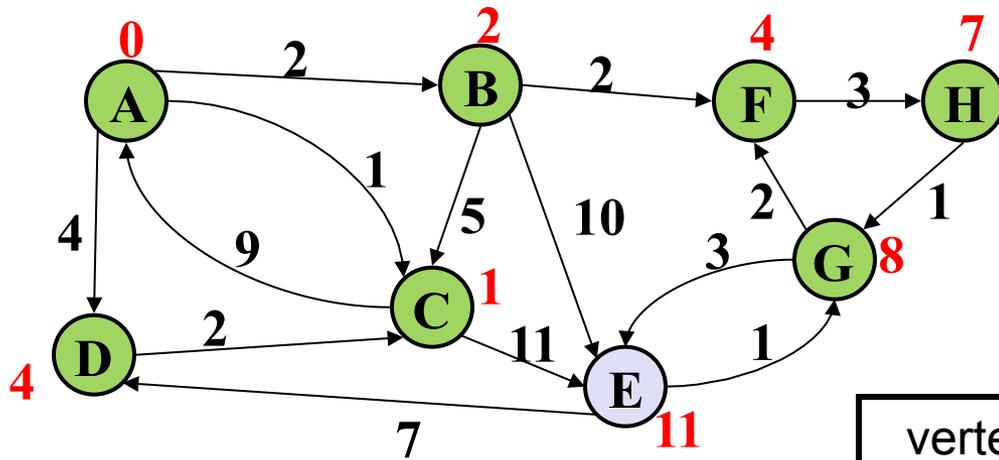

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E		≤ 12	C
F	Y	4	B
G		≤ 8	H
H	Y	7	F

Order Added to Known Set:

A, C, B, D, F, H

Example #1

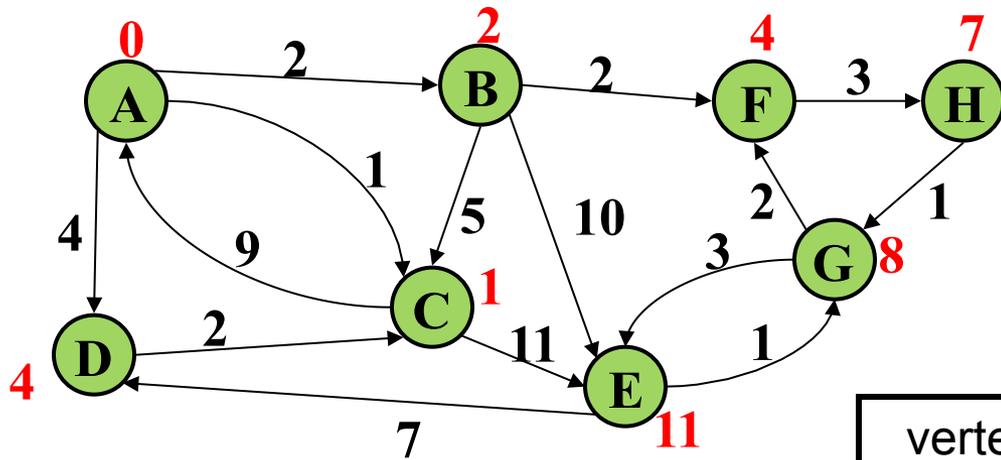

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E		≤ 11	G
F	Y	4	B
G	Y	8	H
H	Y	7	F

Order Added to Known Set:

A, C, B, D, F, H, G

Example #1

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E	Y	11	G
F	Y	4	B
G	Y	8	H
H	Y	7	F

Order Added to Known Set:

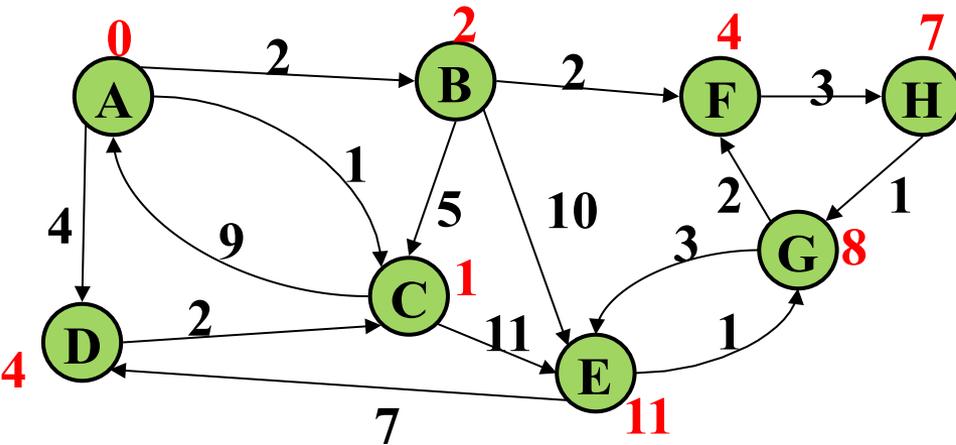

A, C, B, D, F, H, G, E

Features

- When a vertex is marked known,
the cost of the shortest path to that node is known
 - The path is also known by following back-pointers
- While a vertex is still not known,
another shorter path to it **might** still be found

Interpreting the Results

- Now that we're done, how do we get the path from, say, A to E?

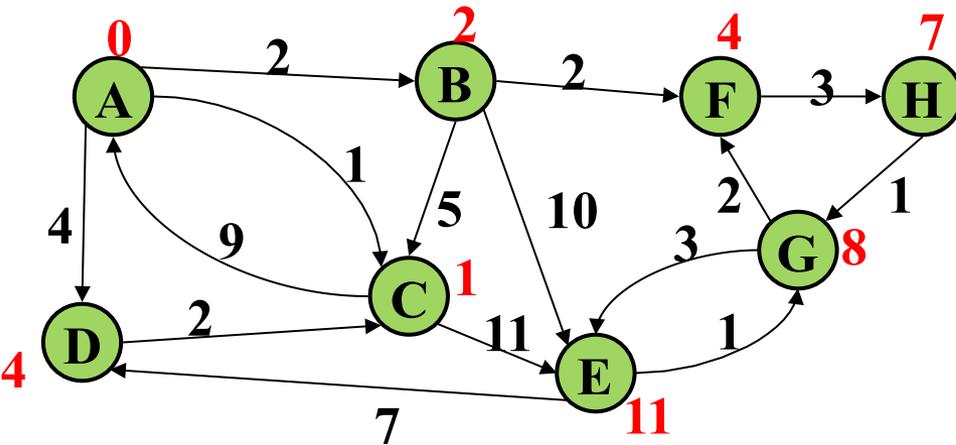

Order Added to Known Set:

A, C, B, D, F, H, G, E

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E	Y	11	G
F	Y	4	B
G	Y	8	H
H	Y	7	F

Stopping Short

- How would this have worked differently if we were only interested in:
 - The path from A to G?
 - The path from A to E?

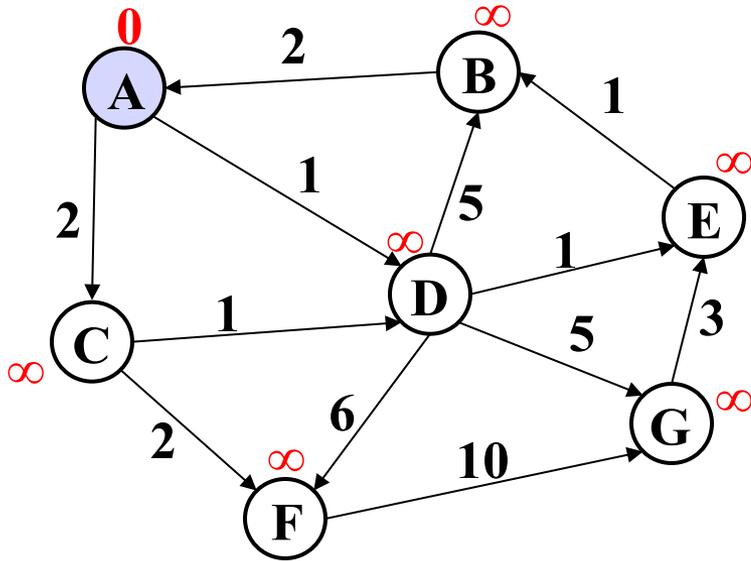

Order Added to Known Set:

A, C, B, D, F, H, G, E

vertex	known?	cost	path
A	Y	0	
B	Y	2	A
C	Y	1	A
D	Y	4	A
E	Y	11	G
F	Y	4	B
G	Y	8	H
H	Y	7	F

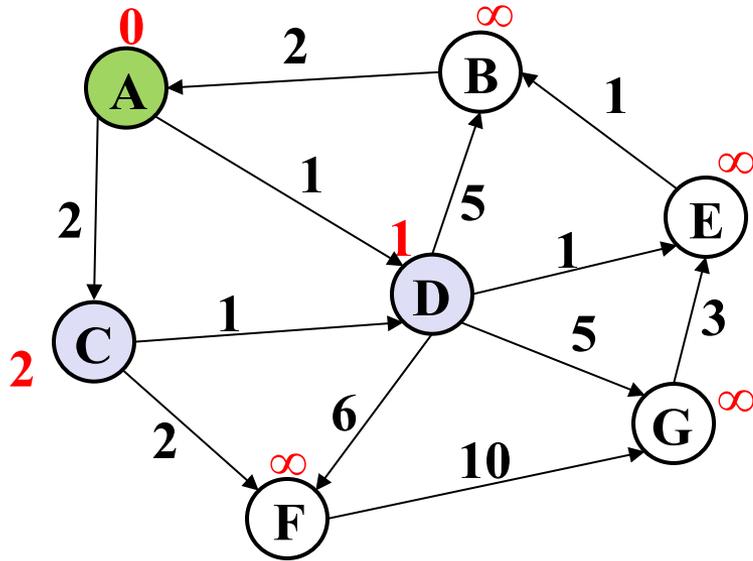

Example #2

Order Added to Known Set:

vertex	known?	cost	path
A		0	
B		??	
C		??	
D		??	
E		??	
F		??	
G		??	

Example #2

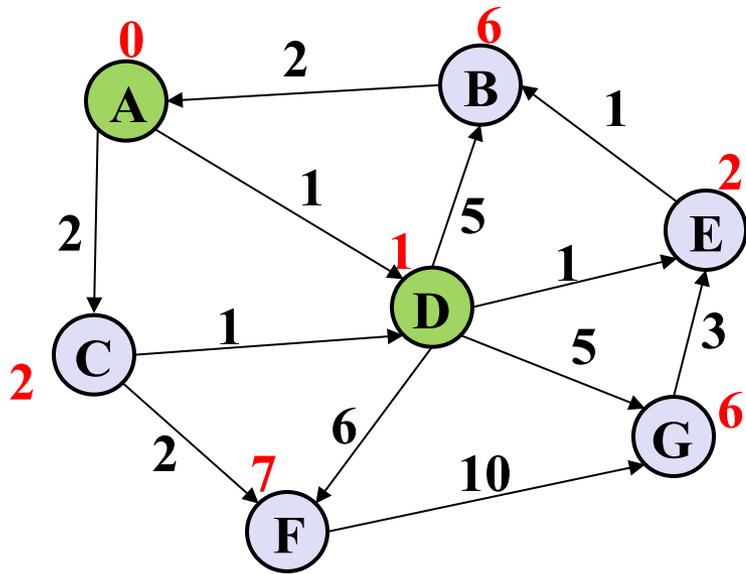

vertex	known?	cost	path
A	Y	0	
B		??	
C		≤ 2	A
D		≤ 1	A
E		??	
F		??	
G		??	

Order Added to Known Set:

A

Example #2

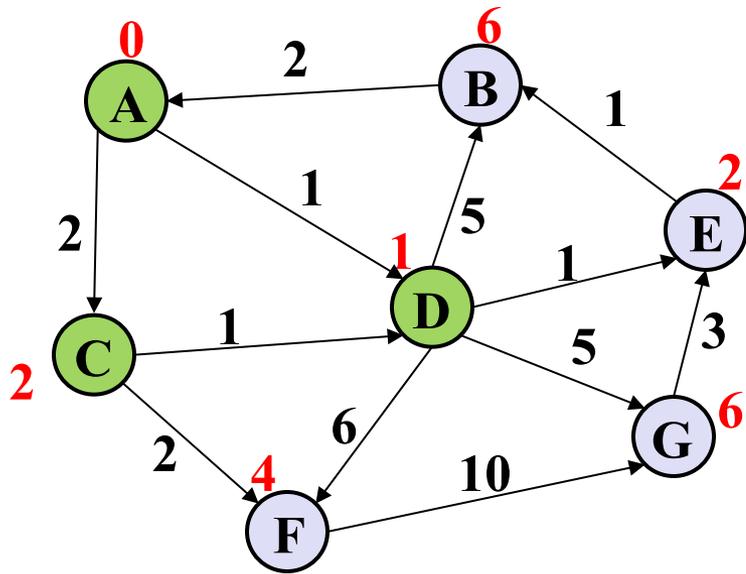

vertex	known?	cost	path
A	Y	0	
B		≤ 6	D
C		≤ 2	A
D	Y	1	A
E		≤ 2	D
F		≤ 7	D
G		≤ 6	D

Order Added to Known Set:

A, D

Example #2

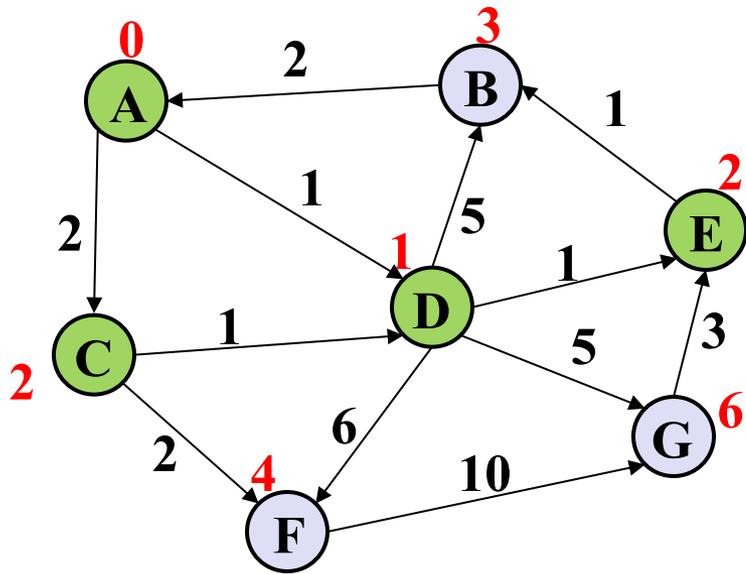

Order Added to Known Set:

A, D, C

vertex	known?	cost	path
A	Y	0	
B		≤ 6	D
C	Y	2	A
D	Y	1	A
E		≤ 2	D
F		≤ 4	C
G		≤ 6	D

Example #2

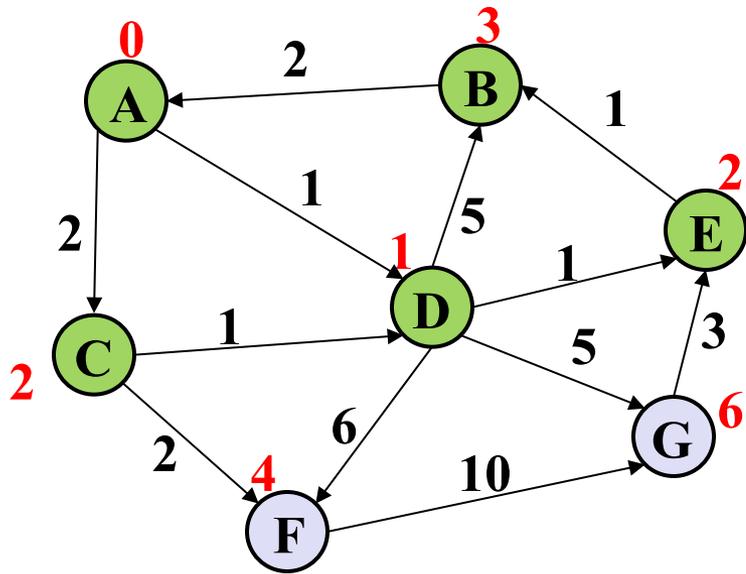

vertex	known?	cost	path
A	Y	0	
B		≤ 3	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F		≤ 4	C
G		≤ 6	D

Order Added to Known Set:

A, D, C, E

Example #2

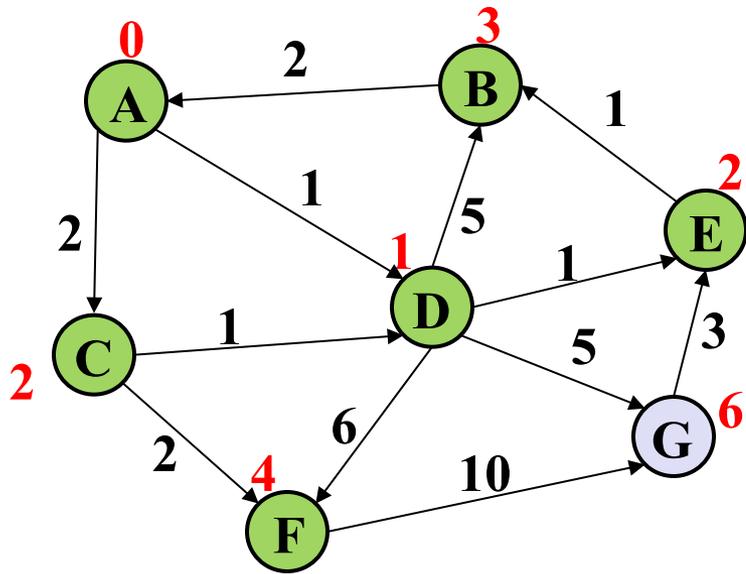

Order Added to Known Set:

A, D, C, E, B

vertex	known?	cost	path
A	Y	0	
B	Y	3	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F		≤ 4	C
G		≤ 6	D

Example #2

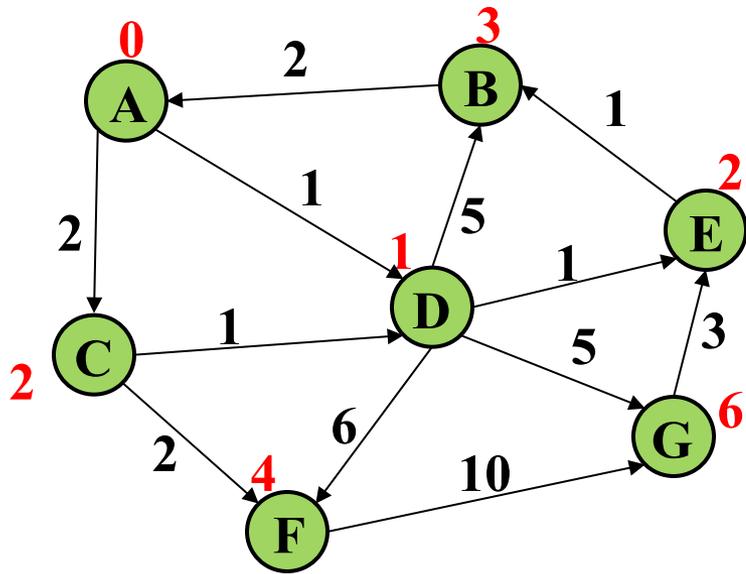

vertex	known?	cost	path
A	Y	0	
B	Y	3	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F	Y	4	C
G		≤ 6	D

Order Added to Known Set:

A, D, C, E, B, F

Example #2

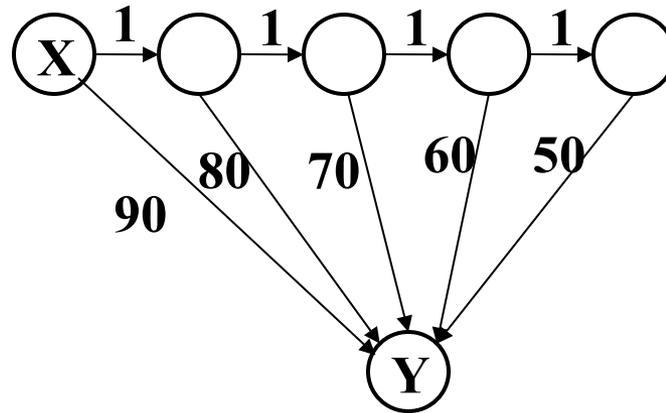

vertex	known?	cost	path
A	Y	0	
B	Y	3	E
C	Y	2	A
D	Y	1	A
E	Y	2	D
F	Y	4	C
G	Y	6	D

Order Added to Known Set:

A, D, C, E, B, F, G

Example #3

How will the best-cost-so-far for Y proceed? 90, 81, 72, 63, 54, ...

Is this expensive? No, each *edge* is processed only once

A Greedy Algorithm

- Dijkstra's algorithm is an example of a *greedy algorithm*:
 - At each step, always does what seems best at that step
 - A locally optimal step, not necessarily globally optimal
 - Once a vertex is known, it is not revisited
 - Turns out to be globally optimal (for this problem)

Where are we?

- Had a problem: Compute shortest paths in a weighted graph with no negative weights
- Learned an algorithm: Dijkstra's algorithm
- What should we do after learning an algorithm?
 - Prove it is correct
 - Not obvious!
 - We will sketch the key ideas
 - Analyze its efficiency
 - Will do better by using a data structure we learned earlier!

Correctness: Intuition

Rough intuition:

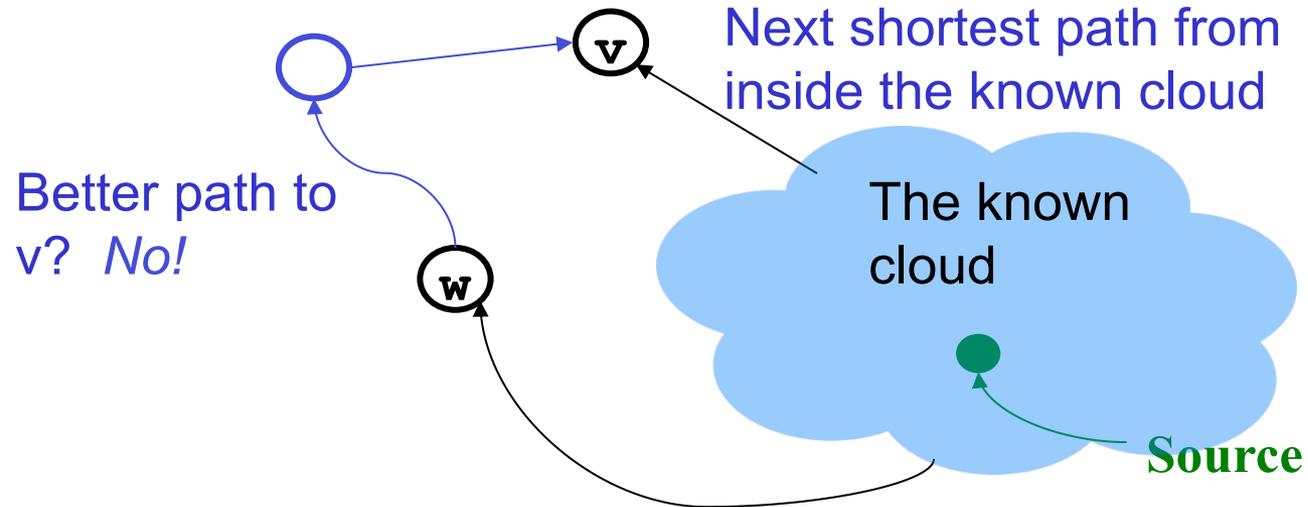

All the “known” vertices have the correct shortest path

- True initially: shortest path to start node has cost 0
- If it stays true every time we mark a node “known”, then by induction this holds and eventually everything is “known”

Key fact we need: When we mark a vertex “known” we won’t discover a shorter path later!

- This holds only because Dijkstra’s algorithm picks the node with the next shortest path-so-far
- The proof is by contradiction...

Correctness: The Cloud (Rough Sketch)

Suppose v is the next node to be marked known (“added to the cloud”)

- The **best-known path** to v must have only nodes “in the cloud”
 - Else we would have picked a node closer to the cloud than v
- Suppose the **actual shortest path** to v is different
 - It won’t use only cloud nodes, or we would know about it
 - So it must use non-cloud nodes. Let w be the *first* non-cloud node on this path. The part of the path up to w is **already known** and must be shorter than the best-known path to v . So v would not have been picked. Contradiction.

Efficiency, first approach

Use pseudocode to determine asymptotic run-time

- Notice each edge is processed only once

```
dijkstra(Graph G, Node start) {  
  for each node: x.cost=infinity, x.known=false  
  start.cost = 0  
  while(not all nodes are known) {  
    b = find unknown node with smallest cost  
    b.known = true  
    for each edge (b,a) in G  
      if(!a.known)  
        if(b.cost + weight((b,a)) < a.cost) {  
          a.cost = b.cost + weight((b,a))  
          a.path = b  
        }  
  }  
}
```

Efficiency, first approach

Use pseudocode to determine asymptotic run-time

- Notice each edge is processed only once

```
dijkstra(Graph G, Node start) {  
  for each node: x.cost=infinity, x.known=false  
  start.cost = 0  
  while(not all nodes are known) {  
    b = find unknown node with smallest cost  
    b.known = true  
    for each edge (b,a) in G  
      if(!a.known)  
        if(b.cost + weight((b,a)) < a.cost) {  
          a.cost = b.cost + weight((b,a))  
          a.path = b  
        }  
  }  
}
```

$O(|V|)$

$O(|V|^2)$

$O(|E|)$

$O(|V|^2)$

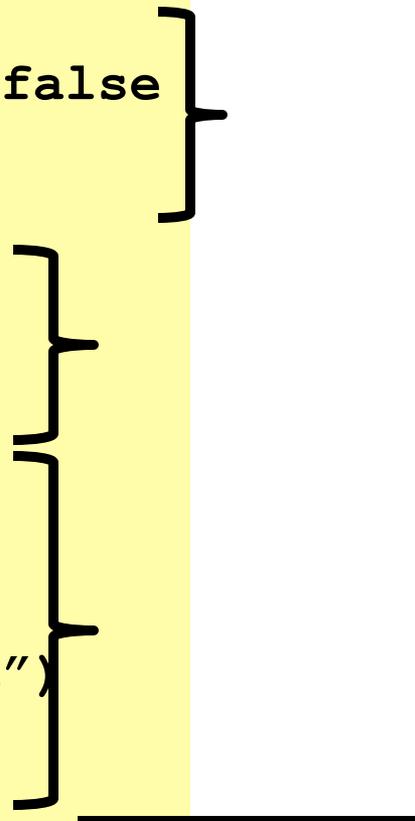

Improving asymptotic running time

- So far: $O(|V|^2)$
- We had a similar “problem” with topological sort being $O(|V|^2)$ due to each iteration looking for the node to process next
 - We solved it with a queue of zero-degree nodes
 - But here we need the lowest-cost node and costs can change as we process edges
- Solution?
 - A priority queue holding all unknown nodes, sorted by cost
 - But must support **decreaseKey** operation
 - Must maintain a reference from each node to its current position in the priority queue
 - Conceptually simple, but can be a pain to code up

Efficiency, second approach

Use pseudocode to determine asymptotic run-time

```
dijkstra(Graph G, Node start) {  
  for each node: x.cost=infinity, x.known=false  
  start.cost = 0  
  build-heap with all nodes  
  while(heap is not empty) {  
    b = deleteMin()  
    b.known = true  
    for each edge (b,a) in G  
      if(!a.known)  
        if(b.cost + weight((b,a)) < a.cost) {  
          decreaseKey(a, "new cost - old cost")  
          a.path = b  
        }  
  }  
}
```

Efficiency, second approach

Use pseudocode to determine asymptotic run-time

```
dijkstra(Graph G, Node start) {  
  for each node: x.cost=infinity, x.known=false  
  start.cost = 0  
  build-heap with all nodes  
  while(heap is not empty) {  
    b = deleteMin()  
    b.known = true  
    for each edge (b,a) in G  
      if(!a.known)  
        if(b.cost + weight((b,a)) < a.cost) {  
          decreaseKey(a, "new cost - old cost")  
          a.path = b  
        }  
  }  
}
```

$O(|V|)$

$O(|V|\log|V|)$

$O(|E|\log|V|)$

$O(|V|\log|V|+|E|\log|V|)$

Dense vs. sparse again

- First approach: $O(|V|^2)$
- Second approach: $O(|V|\log|V|+|E|\log|V|)$
- So which is better?
 - Sparse: $O(|V|\log|V|+|E|\log|V|)$ (if $|E| > |V|$, then $O(|E|\log|V|)$)
 - Dense: $O(|V|^2)$
- But, remember these are worst-case and asymptotic
 - Priority queue might have slightly worse constant factors
 - On the other hand, for “normal graphs”, we might call **decreaseKey** rarely (or not percolate far), making $|E|\log|V|$ more like $|E|$
