

# CSE373: Data Structures and Algorithms

## Lecture 3: Asymptotic Analysis

Kevin Quinn  
Fall 2015

# Gauging performance

- Uh, why not just run the program and time it
  - Too much *variability*, not reliable or *portable*:
    - Hardware: processor(s), memory, etc.
    - Software: OS, Java version, libraries, drivers
    - Other programs running
    - Implementation dependent
  - Choice of input
    - Testing (inexhaustive) may *miss* worst-case input
    - Timing does not *explain* relative timing among inputs (what happens when  $n$  doubles in size)
- Often want to evaluate an *algorithm*, not an implementation
  - Even *before* creating the implementation (“coding it up”)

# Comparing algorithms

When is one *algorithm* (not *implementation*) better than another?

- Various possible answers (clarity, security, ...)
- But a big one is *performance*: for sufficiently large inputs, runs in less time (our focus) or less space

*Large inputs* because probably any algorithm is “plenty good” for small inputs (if  $n$  is 10, probably anything is fast)

Answer will be *independent* of CPU speed, programming language, coding tricks, etc.

Answer is general and rigorous, complementary to “coding it up and timing it on some test cases”

# Analyzing code (“worst case”)

Basic operations take “some amount of” constant time

- Arithmetic (fixed-width)
- Assignment
- Access one Java field or array index
- Etc.

(This is an *approximation of reality*: a very useful “lie”.)

Control Flow	Time required
Consecutive statements	Sum of time of statement
Conditionals	Time of test plus slower branch
Loops	Sum of iterations * time of body
Calls	Time of call’s body
Recursion	Solve <i>recurrence equation</i>

## Example

2	3	5	16	37	50	73	75	126
---	---	---	----	----	----	----	----	-----

Find an integer in a *sorted* array

```
// requires array is sorted
// returns whether k is in array
boolean find(int[] arr, int k){
    ???
}
```

## Linear search

2	3	5	16	37	50	73	75	126
---	---	---	----	----	----	----	----	-----

Find an integer in a *sorted* array

```
// requires array is sorted
// returns whether k is in array
boolean find(int[] arr, int k) {
    for(int i=0; i < arr.length; ++i)
        if(arr[i] == k)
            return true;
    return false;
}
```

Best case: 6ish steps =  $O(1)$   
Worst case: 6ish\*(arr.length)  
=  $O(\text{arr.length})$

# Binary search

2	3	5	16	37	50	73	75	126
---	---	---	----	----	----	----	----	-----

Find an integer in a *sorted* array

- Can also be done non-recursively

```
// requires array is sorted
// returns whether k is in array
boolean find(int[] arr, int k){
    return help(arr,k,0,arr.length);
}
boolean help(int[] arr, int k, int lo, int hi) {
    int mid = (hi+lo)/2; // i.e., lo+(hi-lo)/2
    if(lo==hi)         return false;
    if(arr[mid]==k)    return true;
    if(arr[mid]<k)     return help(arr,k,mid+1,hi);
    else               return help(arr,k,lo,mid);
}
```

# Binary search

Best case: 8ish steps =  $O(1)$

Worst case:  $T(n) = 10ish + T(n/2)$  where  $n$  is `hi-lo`

- $O(\log n)$  where  $n$  is `array.length`
- Solve *recurrence equation* to know that...

```
// requires array is sorted
// returns whether k is in array
boolean find(int[]arr, int k){
    return help(arr,k,0,arr.length);
}
boolean help(int[]arr, int k, int lo, int hi) {
    int mid = (hi+lo)/2;
    if(lo==hi) return false;
    if(arr[mid]==k) return true;
    if(arr[mid]< k) return help(arr,k,mid+1,hi);
    else return help(arr,k,lo,mid);
}
```

# Solving Recurrence Relations

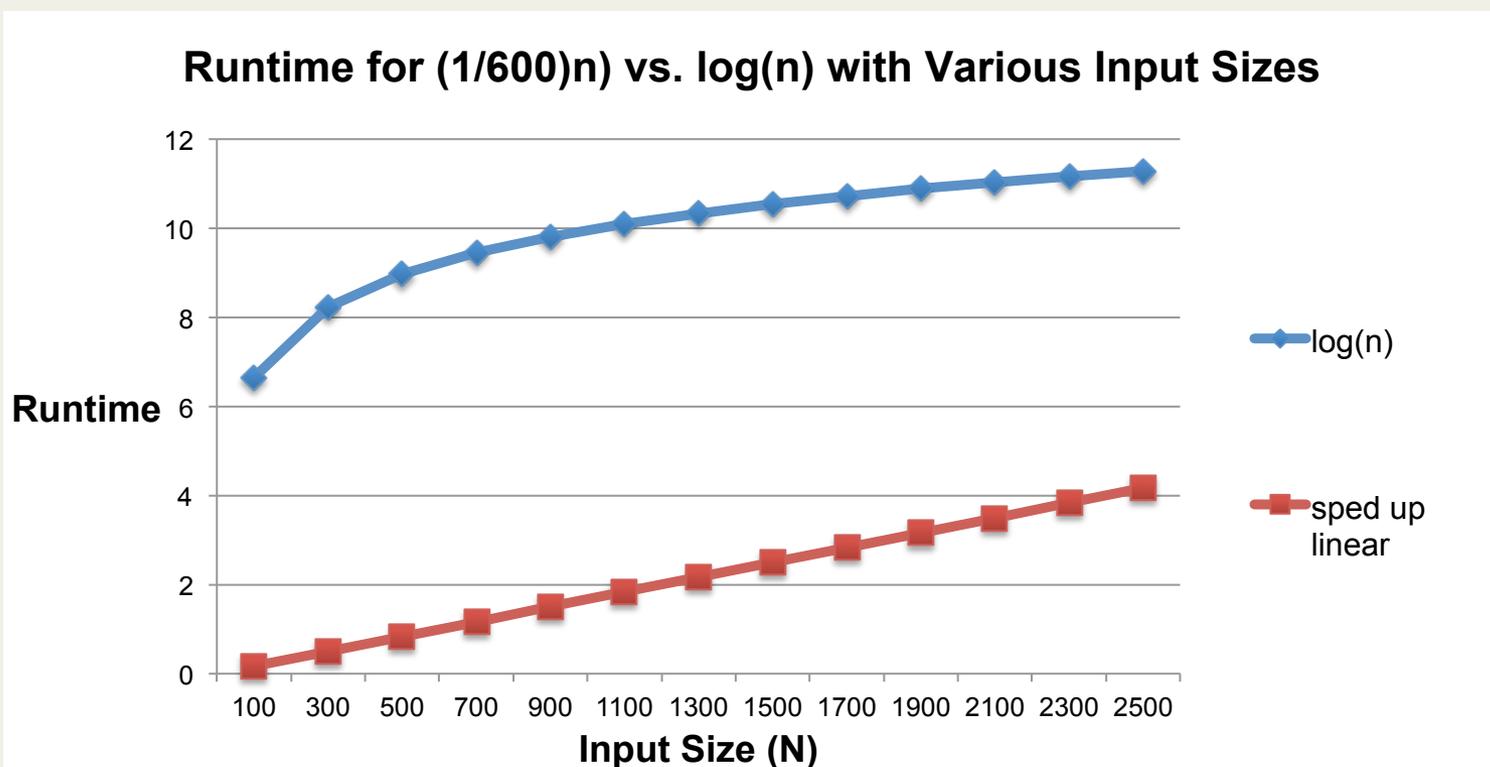

1. Determine the recurrence relation. What is the base case?
  - $T(n) = 10ish + T(n/2) \quad T(1) = 10$
2. “Expand” the original relation to find an equivalent general expression *in terms of the number of expansions*.
  - $T(n) = 10 + 10 + T(n/4)$   
 $= 10 + 10 + 10 + T(n/8)$   
 $= \dots$   
 $= 10k + T(n/(2^k))$
3. Find a closed-form expression by setting *the number of expansions* to a value which reduces the problem to a base case
  - $n/(2^k) = 1$  means  $n = 2^k$  means  $k = \log_2 n$
  - So  $T(n) = 10 \log_2 n + 8$  (get to base case and do it)
  - So  $T(n)$  is  $O(\log n)$

## Ignoring constant factors

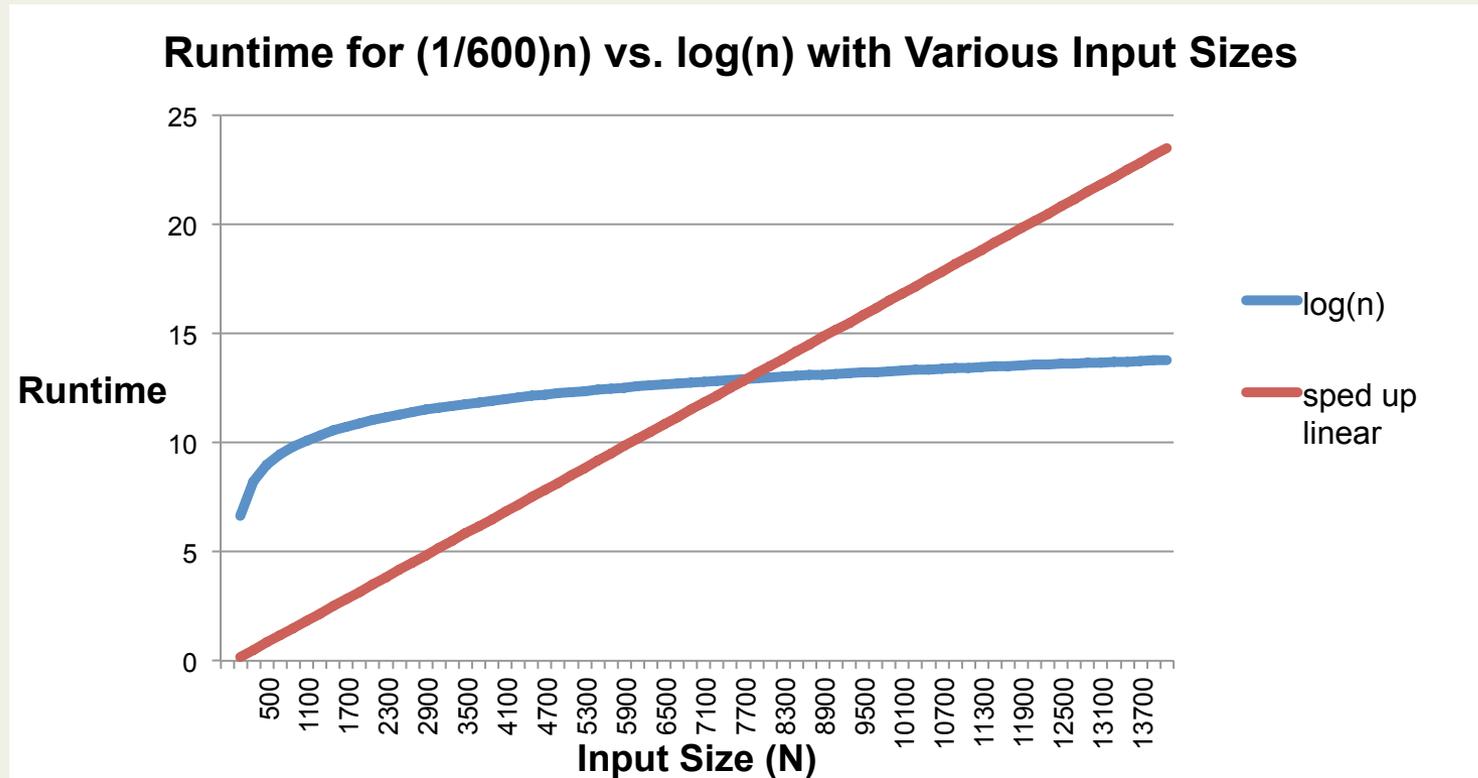

- So binary search is  $O(\log n)$  and linear is  $O(n)$ 
  - But which is faster?
- Could depend on constant factors
  - How *many* assignments, additions, etc. for each  $n$ 
    - E.g.  $T(n) = 5,000,000n$  vs.  $T(n) = 5n^2$
  - And could depend on size of  $n$ 
    - E.g.  $T(n) = 5,000,000 + \log n$  vs.  $T(n) = 10 + n$
- But there exists some  $n_0$  such that for all  $n > n_0$  binary search wins
- Let's play with a couple plots to get some intuition...

# Example

- Let's try to “help” linear search
  - Run it on a computer 100x as fast (say 2015 model vs. 1990)
  - Use a new compiler/language that is 3x as fast
  - Be a clever programmer to eliminate half the work
  - So doing each iteration is 600x as fast as in binary search
- Note: 600x still helpful for problems without logarithmic algorithms!

- Let's try to "help" linear search
  - Run it on a computer 100x as fast (say 2015 model vs. 1990)
  - Use a new compiler/language that is 3x as fast
  - Be a clever programmer to eliminate half the work
  - So doing each iteration is 600x as fast as in binary search
- Note: 600x still helpful for problems without logarithmic algorithms!

## Another example: sum array

Two “obviously” linear algorithms:  $T(n) = O(1) + T(n-1)$

Iterative:

```
int sum(int[] arr) {
    int ans = 0;
    for(int i=0; i<arr.length; ++i)
        ans += arr[i];
    return ans;
}
```

Recursive:

- Recurrence is  
 $k + k + \dots + k$   
for  $n$  times

```
int sum(int[] arr) {
    return help(arr, 0);
}
int help(int[] arr, int i) {
    if(i==arr.length)
        return 0;
    return arr[i] + help(arr, i+1);
}
```

## What about a recursive version?

```
int sum(int[] arr) {
    return help(arr, 0, arr.length);
}
int help(int[] arr, int lo, int hi) {
    if(lo==hi) return 0;
    if(lo==hi-1) return arr[lo];
    int mid = (hi+lo)/2;
    return help(arr, lo, mid) + help(arr, mid, hi);
}
```

Recurrence is  $T(n) = O(1) + 2T(n/2)$

- $1 + 2 + 4 + 8 + \dots$  for  $\log n$  times
- $2^{(\log n)} - 1$  which is proportional to  $n$  (definition of logarithm)

Easier explanation: it adds each number once while doing little else

“Obvious”: You can’t do better than  $O(n)$  – have to read whole array

## Parallelism teaser

- But suppose we could do two recursive calls *at the same time*
  - Like having a friend do half the work for you!

```
int sum(int[] arr) {
    return help(arr, 0, arr.length);
}
int help(int[] arr, int lo, int hi) {
    if (lo == hi) return 0;
    if (lo == hi - 1) return arr[lo];
    int mid = (hi + lo) / 2;
    return help(arr, lo, mid) + help(arr, mid, hi);
}
```

- If you have as many “friends of friends” as needed the recurrence is now  $T(n) = O(1) + 1T(n/2)$ 
  - $O(\log n)$ : same recurrence as for **find**

# Really common recurrences

Should know how to solve recurrences but also recognize some really common ones:

$T(n) = O(1) + T(n-1)$	linear
$T(n) = O(1) + 2T(n/2)$	linear
$T(n) = O(1) + T(n/2)$	logarithmic $O(\log n)$
$T(n) = O(1) + 2T(n-1)$	exponential
$T(n) = O(n) + T(n-1)$	quadratic (see previous lecture)
$T(n) = O(n) + T(n/2)$	linear (why?)
$T(n) = O(n) + 2T(n/2)$	$O(n \log n)$

Note big-Oh can also use more than one variable

- Example: can sum all elements of an  $n$ -by- $m$  matrix in  $O(nm)$

# *Asymptotic notation*

About to show formal definition, which amounts to saying:

1. Eliminate low-order terms
2. Eliminate coefficients

Examples:

- $4n + 5$
- $0.5n \log n + 2n + 7$
- $n^3 + 2^n + 3n$
- $n \log(10n^2)$

# Big-Oh relates functions

We use  $O$  on a function  $f(n)$  (for example  $n^2$ ) to mean *the set of functions with asymptotic behavior less than or equal to  $f(n)$*

So  $(3n^2+17)$  **is in**  $O(n^2)$

- $3n^2+17$  and  $n^2$  have the same asymptotic behavior

Confusingly, we also say/write:

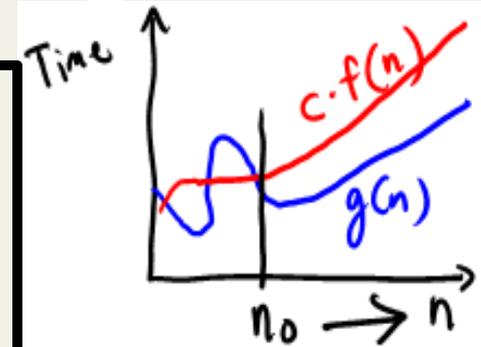

- $(3n^2+17)$  **is**  $O(n^2)$
- $(3n^2+17)$  **=**  $O(n^2)$

But we would never say  $O(n^2) = (3n^2+17)$

# Formally Big-Oh

Definition:

$g(n)$  is in  $O(f(n))$  if there exist constants  $c$  and  $n_0$  such that  $g(n) \leq c f(n)$  for all  $n \geq n_0$

- To show  $g(n)$  is in  $O(f(n))$ , pick a  $c$  large enough to “cover the constant factors” and  $n_0$  large enough to “cover the lower-order terms”
  - Example: Let  $g(n) = 3n^2+17$  and  $f(n) = n^2$   
 $c=5$  and  $n_0=10$  is more than good enough
- This is “less than or equal to”
  - So  $3n^2+17$  is also  $O(n^5)$  and  $O(2^n)$  etc.

## More examples, using formal definition

- Let  $g(n) = 1000n$  and  $f(n) = n^2$ 
  - A valid proof is to find valid  $c$  and  $n_0$
  - The “cross-over point” is  $n=1000$
  - So we can choose  $n_0=1000$  and  $c=1$ 
    - Many other possible choices, e.g., larger  $n_0$  and/or  $c$

Definition:

$g(n)$  is in  $O(f(n))$  if there exist constants  $c$  and  $n_0$  such that  $g(n) \leq c f(n)$  for all  $n \geq n_0$

## More examples, using formal definition

- Let  $g(n) = n^4$  and  $f(n) = 2^n$ 
  - A valid proof is to find valid  $c$  and  $n_0$
  - We can choose  $n_0=20$  and  $c=1$

Definition:

$g(n)$  is in  $O(f(n))$  if there exist constants  $c$  and  $n_0$  such that  $g(n) \leq c f(n)$  for all  $n \geq n_0$

## What's with the $c$

- The constant multiplier  $c$  is what allows functions that differ only in their largest coefficient to have the same asymptotic complexity
- Example:  $g(n) = 7n+5$  and  $f(n) = n$ 
  - For any choice of  $n_0$ , need a  $c > 7$  (or more) to show  $g(n)$  is in  $O(f(n))$

Definition:

$g(n)$  is in  $O(f(n))$  if there exist constants  $c$  and  $n_0$  such that  $g(n) \leq c f(n)$  for all  $n \geq n_0$

## *What you can drop*

- Eliminate coefficients because we don't have units anyway
  - $3n^2$  versus  $5n^2$  doesn't mean anything when we have not specified the cost of constant-time operations (can re-scale)
- Eliminate low-order terms because they have vanishingly small impact as  $n$  grows
- Do NOT ignore constants that are not multipliers
  - $n^3$  is not  $O(n^2)$
  - $3^n$  is not  $O(2^n)$

(This all follows from the formal definition)

## Big-O: Common Names (Again)

$O(1)$	constant
$O(\log n)$	logarithmic
$O(n)$	linear
$O(n \log n)$	“ $n \log n$ ”
$O(n^2)$	quadratic
$O(n^3)$	cubic
$O(n^k)$	polynomial (where $k$ is any constant)
$O(k^n)$	exponential (where $k$ is any constant $> 1$ )

“exponential” does not mean “grows really fast”, it means “grows at rate proportional to  $k^n$  for some  $k > 1$ ”

- A savings account accrues interest exponentially ( $k=1.01$ ?)
- If you don't know  $k$ , you probably don't know it's exponential

# More Asymptotic Notation

- Upper bound:  $O(f(n))$  is the set of all functions asymptotically less than or equal to  $f(n)$ 
  - $g(n)$  is in  $O(f(n))$  if there exist constants  $c$  and  $n_0$  such that  $g(n) \leq c f(n)$  for all  $n \geq n_0$
- Lower bound:  $\Omega(f(n))$  is the set of all functions asymptotically greater than or equal to  $f(n)$ 
  - $g(n)$  is in  $\Omega(f(n))$  if there exist constants  $c$  and  $n_0$  such that  $g(n) \geq c f(n)$  for all  $n \geq n_0$
- Tight bound:  $\theta(f(n))$  is the set of all functions asymptotically equal to  $f(n)$ 
  - Intersection of  $O(f(n))$  and  $\Omega(f(n))$  (use *different*  $c$  values)

## Correct terms, in theory

A common error is to say  $O(f(n))$  when you mean  $\theta(f(n))$

- Since a linear algorithm is also  $O(n^5)$ , it's tempting to say “this algorithm is exactly  $O(n)$ ”
- That doesn't mean anything, say it is  $\theta(n)$
- That means that it is not, for example  $O(\log n)$

Less common notation:

- “little-oh”: intersection of “big-Oh” and *not* “big-Theta”
  - For all  $c$ , there exists an  $n_0$  such that...  $\leq$
  - Example: array sum is  $o(n^2)$  but not  $o(n)$
- “little-omega”: intersection of “big-Omega” and *not* “big-Theta”
  - For all  $c$ , there exists an  $n_0$  such that...  $\geq$
  - Example: array sum is  $\omega(\log n)$  but not  $\omega(n)$

# What we are analyzing

- The most common thing to do is give an  $O$  or  $\theta$  **bound** to the **worst-case** running **time** of an **algorithm**
- Example: binary-search algorithm
  - Common:  $\theta(\log n)$  running-time in the worst-case
  - Less common:  $\theta(1)$  in the best-case (item is in the middle)
  - Less common (but very good to know): the find-in-sorted-array **problem** is  $\Omega(\log n)$  in the worst-case
    - No algorithm can do better
    - A **problem** cannot be  $O(f(n))$  since you can always find a slower algorithm, but can mean **there exists** an algorithm

## Other things to analyze

- Space instead of time
  - Remember we can often use space to gain time
- Average case
  - Sometimes only if you assume something about the *probability distribution* of inputs
  - Sometimes uses randomization in the algorithm
    - Will see an example with sorting
  - Sometimes an *amortized guarantee*
    - Average time over any sequence of operations
    - Will discuss in a later lecture

# Summary

Analysis can be about:

- The problem or the algorithm (usually algorithm)
- Time or space (usually time)
  - Or power or dollars or ...
- Best-, worst-, or average-case (usually worst)
- Upper-, lower-, or tight-bound (usually upper or tight)

## Usually asymptotic is valuable

- Asymptotic complexity focuses on behavior for large  $n$  and is independent of any computer / coding trick
- But you can “abuse” it to be misled about trade-offs
- Example:  $n^{1/10}$  vs.  $\log n$ 
  - Asymptotically  $n^{1/10}$  grows more quickly
  - But the “cross-over” point is around  $5 * 10^{17}$
  - So if you have input size less than  $2^{58}$ , prefer  $n^{1/10}$
- For *small*  $n$ , an algorithm with worse asymptotic complexity might be faster
  - Here the constant factors can matter, if you care about performance for small  $n$

# *Timing vs. Big-Oh Summary*

- Big-oh is an essential part of computer science's mathematical foundation
  - Examine the algorithm itself, not the implementation
  - Reason about (even prove) performance as a function of  $n$
- Timing also has its place
  - Compare implementations
  - Focus on data sets you care about (versus worst case)
  - Determine what the constant factors “really are”
