Algorithm Design Techniques

- Greedy
 - Shortest path, minimum spanning tree, ...
- Divide and Conquer
 - Divide the problem into smaller subproblems, solve them, and combine into the overall solution
 - Often done recursively
 - Quick sort, merge sort are great examples
- Dynamic Programming
 - Brute force through all possible solutions, storing solutions to subproblems to avoid repeat computation
- Backtracking
 - A clever form of exhaustive search

Backtracking: Idea

- Backtracking is a technique used to solve problems with a large search space, by systematically trying and eliminating possibilities.
- A standard example of backtracking would be going through a maze.
 - At some point, you might have two options of which direction to go:

Backtracking

One strategy would be to try going through **Portion A** of the maze.

If you get stuck before you find your way out, then you "*backtrack*" to the junction.

At this point in time you know that **Portion A** will *NOT* lead you out of the maze, so you then start searching in **Portion B**

Backtracking

- Clearly, at a single junction you could have even more than 2 choices.
- The backtracking strategy says to try each choice, one after the other,
 - if you ever get stuck, "*backtrack*" to the junction and try the next choice.
- If you try all choices and never found a way out, then there IS no solution to the maze.

Backtracking (animation)

Backtracking

- Dealing with the maze:
 - From your start point, you will iterate through each possible starting move.
 - From there, you recursively move forward.
 - If you ever get stuck, the recursion takes you back to where you were, and you try the next possible move.
- Make sure you don't try too many possibilities,
 - Mark which locations in the maze have been visited already so that no location in the maze gets visited twice.
 - If a place has already been visited, there is no point in trying to reach the end of the maze from there again.

Backtracking

The neat thing about coding up backtracking is that it can be done recursively, without having to do all the bookkeeping at once.

- Instead, the stack of recursive calls does most of the bookkeeping
- (i.e., keeps track of which locations we've tried so far.)

On to Complexity theory!

The \$1M question

The P versus NP problem (*informally*)

Can every problem whose solution can be *quickly verified* by a computer also be *quickly solved* by a computer?

What is an efficient algorithm?

Is an $O(n)$ algorithm efficient?

How about $O(n \log n)$?

$O(n^2)$?

$O(n^{10})$?

$O(n^{\log n})$?

$O(2^n)$?

$O(n!)$?

polynomial time

$O(n^c)$ for some
constant c

non-polynomial
time

The Class P (polynomial time)

NP (Nondeterministic Polynomial Time)

The P versus NP problem

Is one of the biggest open problems in computer science (and mathematics) today

It's currently unknown whether there exist polynomial time algorithms for NP-complete problems

- We know $P \subseteq NP$, but does $P = NP$?
- People generally believe $P \neq NP$, but no proof yet

What do these NP problems look like?

Does there exist an algorithm for solving $n \times n \times n$ Sudoku that runs in time $p(n)$ for some polynomial $p(\)$?

■
■
■

$n \times n \times n$

The P versus NP problem (**informally**)

Can every problem whose solution can be **verified**
in polynomial time by a computer also be **solved**
in polynomial time by a computer?

To check if a problem is in NP

- Phrase the problem as a yes/no question
 - If we can prove any yes instance is correct (in polynomial time), it is in NP
 - If we can **also** answer yes or no to the problem (in polynomial time) without being given a solution, it is in P

The Class P

The class of all sets that can be
verified in polynomial time.

AND

The class of all decision
problems that can be
decided in polynomial time.

P

Binary Search

Dijkstra's Algorithm

Breadth-First Search

Sorting Algorithms

NP

The class of all sets that
can be **verified** in
polynomial time.

Sudoku

Input: $n \times n \times n$ sudoku instance

Output: YES if this sudoku has a solution

NO if it does not

The Set “SUDOKU”

$\text{SUDOKU} = \{ \text{All solvable sudoku instances} \}$

Hamilton Cycle

Given a graph $G = (V, E)$, is there a cycle that visits all the nodes exactly once?

YES if G has a Hamilton cycle

NO if G has no Hamilton cycle

The Set “HAM”

$\text{HAM} = \{ \text{graph } G \mid G \text{ has a Hamilton cycle} \}$

Circuit-Satisfiability

Input: A circuit C with one output

Output: YES if C is satisfiable

NO if C is not satisfiable

The Set “SAT”

$SAT = \{ \text{all satisfiable circuits } C \}$

Verifying Membership

Is there a short “proof” I can give you to **verify** that:

$G \in \text{HAM?}$

$G \in \text{Sudoku?}$

$G \in \text{SAT?}$

Yes: I can just give you the cycle, solution, circuit

The Class NP

The class of sets for which there exist
“short” proofs of membership
(of polynomial length)
that can “quickly” verified
(in polynomial time).

Fact: $P \subseteq NP$

Recall: The algorithm doesn't have to find the proof; it just needs to be able to verify that it is a “correct” proof.

Summary: P versus NP

NP: “proof of membership” in a set can be **verified** in polynomial time.

P: in NP (membership verified in polynomial time)

AND membership in a set can be **decided** in polynomial time.

Fact: $P \subseteq NP$

Question: Does $NP \subseteq P$?

i.e. ***Does $P = NP$?***

People generally believe $P \neq NP$, but no proof yet

Why Care?

NP Contains Lots of Problems We Don't Know to be in P

Classroom Scheduling

Packing objects into bins

Scheduling jobs on machines

Finding cheap tours visiting a subset of cities

Finding good packet routings in networks

Decryption

...

OK, OK, I care...

How could we prove that $NP = P$?

We would have to show that every set in NP has a polynomial time algorithm...

How do I do that?

It may take a long time!

Also, what if I forgot one of the sets in NP?

How could we prove that $NP = P$?

We can describe **just one** problem L in NP , such that if this problem L is in P , then $NP \subseteq P$.

It is a problem that can capture all other problems in NP .

The “Hardest” Set in NP

We call these problems **NP -complete**

Theorem [Cook/Levin]

SAT is one problem in NP, such that if we can show SAT is in P, then we have shown $NP = P$.

SAT is a problem in NP that can capture all other languages in NP.

We say SAT is **NP-complete**.

Poly-time reducible to each other

NP-complete: The “Hardest” problems in NP

Sudoku

Clique

SAT

Independent-Set

3-Colorability

HAM

These problems are all “polynomial-time equivalent”
i.e., each of these can be reduced to any of the others
in polynomial time

If you get a polynomial-time algorithm for one,
you get a polynomial-time algorithm for ALL.
(you get millions of dollars, you solve decryption, ... etc.)
