Lecture 11 – gdb and Debugging

---

# Agenda

---

- Debuggers, particularly gdb
- Why?
  - To learn general features of breakpoint-debugging
  - To learn specifics of gdb
  - To learn general debugging “survival skills”
    - Skill #1: don’t panic!

# An execution monitor?

---

- What would you like to “see from” and “do to” a running program?
- Why might all that be helpful?
- What are reasonable ways to debug a program?
- A “debugger” is a tool that lets you stop running programs, inspect (sometimes set) values, etc.
  - A “CAT scan” for observing executing code

# Issues

---

- Source information for compiled code. (Get compiler help)
- Stopping your program too late to find the problem. (Art)
- Trying to “debug” the wrong algorithm
- Trying to “run the debugger” instead of understanding the program
- It’s an important tool
- Debugging C vs. Java
  - Eliminating crashes does not make your C program correct
  - Debugging Java is “easier” because (some) crashes and memory errors do not exist
  - But programming Java is “easier” for the same reason!

# `gdb`

---

- `gdb` (Gnu debugger) is part of the standard Linux toolchain.
- `gdb` supports several languages, including C compiled by `gcc`.
- Modern IDEs have fancy GUI interfaces, which help, but concepts are the same.
- Compiling with debugging information: `gcc -g`
  - Otherwise, `gdb` can tell you little more than the stack of function calls.
- Running `gdb`: `gdb executable`
  - Source files should be in same directory (or use the `-d` flag).
- At prompt: `run args`
- Note: You can also inspect core files, which is why they get saved.
  - (Mostly useful for analyzing crashed programs after-the-fact, not for systematic debugging. The original use of `db`.)

# Basic functions

---

- backtrace
- frame, up, down
- print expression, info args, info locals

Often enough for “crash debugging”

Also often enough for learning how “the compiler does things” (e.g., stack direction, malloc policy, ...)

# Breakpoints

---

- break function (or line-number or ...)
- conditional breakpoints (break XXX if expr)
  1. to skip a bunch of iterations
  2. to do assertion checking
- going forward: continue, next, step, finish
  - Some debuggers let you “go backwards” (typically an illusion)
- Often enough for “binary search debugging”
- Also useful for learning program structure (e.g., when is some function called)
- Skim the manual for other features.

# A few tricks

---

- Everyone develops their own “debugging tricks”; here are a few:
  - Printing pointer values to see how big objects were.
  - Always checking why a seg-fault happened (infinite stack and array-overflow very different)
  - “Staring at code” even if it does not crash
  - Printing array contents (especially last elements)
  - . . .

# Advice

---

- Understand what the tool provides you
- Use it to accomplish a task, for example “I want to know the call-stack when I get the NULL-pointer dereference”
- Optimize your time developing software
  - Think of debugging as a systematic experiment to discover what’s wrong — not a way to randomly poke around
- Use development environments that have debuggers?
- See also: jdb for Java
- Like any tool, takes extra time at first but designed to save you time in the long run
  - Education is an investment

# gdb summary – running programs

- Be sure to compile with `gcc -g`
- Open the program with: `gdb <executable file>`
- Start or restart the program: `run <command args>`
- Quit the program: `kill`
- Quit gdb: `quit`
- Reference information: `help`
  
- Most commands have short abbreviations
- `<return>` often repeats the last command
  - Particularly useful when stepping through code

# gdb summary – looking around

- bt – stack backtrace
- up, down – change current stack frame
- list – display source code (list n, list <function name>)
- print expression – evaluate and print expression
- display expression –(re-)evaluate and print expression every time execution pauses.
  - undisplay – remove an expression from this recurring list.

# gdb summary – breakpoints, stepping

---

- break – set breakpoint. (break <function name>, break <linenumber>, break <file>:<linenumber>)
- info break – print table of currently set breakpoints
- clear – remove breakpoints
- disable/enable – temporarily turn breakpoints off/on without removing them from the breakpoint table
  
- continue – resume execution to next breakpoint or end of program
- step – execute next source line
- next – execute next source line, but treat function calls as a single statement and don't step into them
- finish – execute to the conclusion of the current function
  - How to recover if you meant “next” instead of “step”
