

CSE 374 Lecture 3

Emacs and I/O Redirection

HWo

- Due on Monday
- Goal: ensure that you are able to use the fundamental tools we need for this course
 - ◆ If you have problems, follow up to correct them ASAP.
- Debugging: in this course you need to work more independently. Use all the resources you have to find answers.
 - ◆ Ex: scp - how could you figure out that command?
- If you added the course late: You will have two days from when you get your klaatu account to complete the exercise before it uses a 'late day'.

Bash Language

- Bash acts as a language interpreter
 - Commands are subroutines with arguments
 - Bash interprets the arguments & calls subroutine
 - Bash also has its own variables and logic

*BASH applies its own processing
to the I/O text - 'globbing'*

Shell Behavior

All redirection & string expansion or substitutions are done by the shell, before the command.

Command only sees resulting I/O streams.

Special characters

❖ Directory shortcuts

- ~uname, ~
- ./ or ../

❖ Wildcards (globbing)

- 0 or more chars: *
- Exactly one char: ?
- Specified chars: [A-Z]

❖ History, or '!'

Special Characters

! > < & | * ~ [] “ ‘ ` \$ /

\ is escape
character

“string”

‘string’

What do they all
mean?

Would substitute
things like \$VAR

Suppresses
substitutions

I/O Streams

- All bash commands have three streams
 - 0- stdin [keyboard]
 - 1- stdout [screen]
 - 2-stderr [screen]
- Can redirect streams
 - < yourInput
 - > yourOutput
 - >> appendYourOutput
 - 2> yourError
 - &> yourOutput&Error
 - And more...
- Special File /dev/null
 - Is EOF if input
 - Data is discarded if output
- Can combine one cmd to the next
 - Cmd1 | cmd2 - pipe output of cmd1 into input of cmd2
 - Cmd1; cmd2 - do one after another
 - Cmd1 `cmd2` - use output of cmd2 as argument to cmd1
- Can use cmd logic
 - Cmd1 || cmd2 - do cmd2 if cmd1 fails
 - Cmd1 && cmd2 - do cmd 2 if cmd1 succeeds

3.5.4 Command Substitution

Command substitution allows the output of a command to replace the command itself. Command substitution occurs when a command is enclosed as follows:

```
$(command)
```

or

```
`command`
```

by executing *command* in a subshell environment and replacing the command substitution with the output, with any trailing newlines deleted. Embedded newlines are not deleted, but they may be removed. Command substitution `$(cat file)` can be replaced by the equivalent but faster `<(cat file)`.

When the backquoted form of substitution is used, backslash retains its literal meaning except when followed by `'`, `"`, or `\`. A backslash followed by a backslash terminates the command substitution. When using the `$(command)` form, all characters are treated literally; none are treated specially.

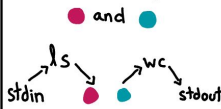

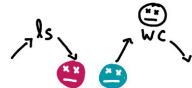

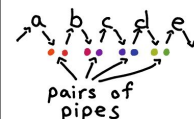

When command substitution is nested, to nest when using the backquoted form, escape the inner backquotes with backslashes.

When using the `$(command)` form, word splitting and filename expansion are not performed on the results.

pipes

JULIA EVANS
@b0rk

drawings.jvns.ca

<p>Sometimes you want to send the <u>output</u> of one process to the <u>input</u> of another</p> <pre>\$ ls wc -l</pre> <p>53 ← 53 files!</p>	<p>a pipe is a pair of 2 magical file descriptors</p> <p>● and ●</p> 	<p>When <code>ls</code> does <code>write(●, "hi")</code> <code>wc</code> can read it! <code>read(●)</code> → "hi"</p>
<p>pipe buffers</p> <p><code>ls</code> "I'm gonna write a bajillion bytes to ●"</p> <p>"uh no if my buffer is full you have to wait" ●</p>	<p>what if your target process dies?</p>  <p><code>ls</code> gets sent SIGPIPE if ● gets closed (<code>ls</code> usually dies)</p>	<p>you can pipe SO MANY things together</p> <pre>\$ a b c d e</pre>  <p>pairs of pipes</p>

Some Bash redirection syntax

redirect stdout to a file →	<i>command > output</i>
redirect stderr to a file	<i>command 2> output</i>
redirect stdout to stderr	<i>command 1>&2 output</i>
redirect stderr to stdout	<i>command 2>&1 output</i>
redirect stderr and stdout to a file	<i>command &> output</i>

Reading: [Bash Redirections](#) (spec), [bash hackers redirections](#) (examples)

Alias

Defines a shortcut or 'alias' to a command.

Also, 'alias'

.bashrc

(Essentially a really easy script)

Towards Scripts

- Shell has a state (working directory, user, aliases, history, streams)
- Can expand state with variables
- ‘Source’ runs a file and changes state
- Can run a file without changing state by running script in new shell.

Emacs (text editor)

C-x C-s #save

C-x C-c # quit

C-e # go to end of line

C-a # go to beginning of line

C-x C-f # find a file

C-g #exit menu

C-x C-k # kill a buffer

You can use any text editor you like. Emacs is amazingly powerful, and highly customizable with lisp scripts. It is probably worth learning.

Okay, lets make a script!

1. First line of file is `#!/bin/bash` (specifies which interpreter to execute)
2. Make file executable (`chmod u+x`)
3. Run a file `./myNewScript`
4. Shell sees the shell program (`/bin/bash`) and launches it to run the script
5. Can include
 - a. String tests (string returns true if non-zero length, `string < string`, etc.)
 - b. Logic (`&&`, `||`, `!`) - use double brackets
 - c. File tests (`-d` : is directory, `-f`: is file, `-w`: file has write permission etc.)
 - d. Math - use double parens

Script Arguments & Errors

Script refers to i^{th} argument at $\$i$; $\$0$ is the program

Use 'shift' to move arguments towards left ($\$i$ become $\$i-n$)

Exit your shell with 0 (normal) or 1 (error)

Variables & Alias

Define variable

```
i=15
```

Access variable

```
$i
```

Undefined variable is empty string

```
Alias cheer="echo yahoo\!"
```
