

CSE 374 Programming Concepts and Tools

Lecture 23 - Concurrency

This Week

Monday: C++ Smart Pointers

Wednesday: C++ Inheritance

Today: Concurrency

Today

Example: Building Search Engine

Why we need more than sequential code

Threads

Concurrency

Data Races

Honorable Mention: Thread Pools

Building a Web Search Engine

We have:

- An index (similar to database)
 - A map from *<word>* to *<list of documents containing the word>*
 - This is probably *shared* over multiple files
- A query processor
 - Accepts a query composed of multiple words
 - Looks up each word in the index
 - Merges the result from each word into an overall result set

Search Engine Architecture

Sequential Code For Query Processing

Pseudocode:

```
listen_fd = Listen(port);  
  
while (1) {  
    client_fd = accept(listen_fd);  
    buf = read(client_fd);  
    resp = ProcessQuery(buf);  
    write(client_fd, resp);  
    close(client_fd);  
}
```

Execution Timeline: To Scale

Sequential Queries – Simplified

Sequential Is Inefficient

Only one query is being processed at a time

- All other queries queue up behind the first one
- And clients queue up behind the queries ...

Even while processing one query, the CPU is idle the vast majority of the time

- It is **blocked** waiting for I/O to complete
 - Disk I/O can be very, very slow (10 million times slower ...)

At most one I/O operation is in flight at a time

- Missed opportunities to speed I/O up
 - Separate devices in parallel, better scheduling of a single device, etc.

Concurrency

Our search engine could run concurrently:

- Example: Execute queries one at a time, but issue *I/O requests* against different files/disks simultaneously
 - Could read from several index files at once, processing the I/O results as they arrive
- Example: Our web server could execute multiple *queries* at the same time
 - While one is waiting for I/O, another can be executing on the CPU

Concurrency != Parallelism

- Concurrency is doing multiple tasks at a time
 - one person (or more) cooking multiple dishes at the same time
- Parallelism is executing multiple CPU instructions *simultaneously*
 - having *multiple* people (possibly cooking the same dish)

A Concurrent Implementation

Use multiple “workers”

- As a query arrives, create a new “worker” to handle it
 - The “worker” reads the query from the network, issues read requests against files, assembles results and writes to the network
 - The “worker” uses blocking I/O; the “worker” alternates between consuming CPU cycles and blocking on I/O
- The OS context switches between “workers”
 - While one is blocked on I/O, another can use the CPU
 - Multiple “workers” I/O requests can be issued at once

Threads

—

Review: Processes

The components of a “process” are:

- Resources such as file descriptors and network sockets
- An address space

Different Processes have independent components:

- Most importantly: Isolated address spaces.
- Every process thinks it has access to the machine’s entire memory
- [Memory Virtualization](#)

An address space of a process can hold stack(s) that distinguish different “threads” of execution.

**A process
in memory**

Introducing Threads

Separate the concept of a **process** from the “thread of execution”

- Usually called a **thread**, this is a sequential execution stream within a process
- Threads are contained within a process; **process > thread**

In most modern OS's:

- Threads are the **unit of scheduling**

Once we have the idea of “threads” separate from “processes”, we arrive at a world where a process can have multiple threads.

Multi-threaded Search Engine (Pseudocode)

```
main() {  
    while (1) {  
        string query_words[] = GetNextQuery();  
        CreateThread(ProcessQuery(query_words));  
    }  
}
```

```
doclist Lookup(string word) {  
    bucket = hash(word);  
    hitlist = file.read(bucket);  
    foreach hit in hitlist  
        doclist.append(file.read(hit));  
    return doclist;  
}  
  
ProcessQuery(string query_words[]) {  
    results = Lookup(query_words[0]);  
    foreach word in query[1..n]  
        results = results.intersect(Lookup(word));  
    Display(results);  
}
```

Multi-threaded Search Engine (Execution)

Still on one CPU/one core – just no overlapping CPU executions (blue).

Why Threads?

Advantages:

- You (mostly) write sequential-looking code
- Threads can run in parallel if you have multiple CPUs/cores
 - AKA, on most modern computers
 - Definitely on Cancun :)

Disadvantages:

- If threads share data, you need **locks** or other **synchronization**
 - Very bug-prone and difficult to debug
- Threads can introduce overhead
 - Lock contention, context switch overhead, and other issues
- Need language support for threads

Threads vs. Processes

In most modern OS's:

- A **Process** has a unique: address space, OS resources, and security attributes
- A **Thread** has a unique: stack, stack pointer, program counter, and registers
- Threads are the *unit of scheduling* and processes are their *containers*; every process has at least one thread running in it

Questions?

Threads vs. Processes

Single-Threaded Address Spaces

Before creating a thread

- One thread of execution running in the address space
 - One stack
- That main thread invokes a function to create a new thread
 - Typically `pthread_create()`

Multi-threaded Address Spaces

After creating a thread

- Two threads of execution running in the address space
 - Original thread (parent) and new thread (child)
 - New stack created for child thread
 - Child thread has its own **stack**
- Both threads share the other segments (code, heap, globals)
 - They can cooperatively modify shared data

POSIX Threads (pthreads)

POSIX = Portable Operating System Interface

- A family of standards specified by IEEE for maintaining compatibility among operating systems.
- `ls`, `cd`, `grep`, `find`, etc. are all POSIX commands.

The POSIX APIs for dealing with threads

- Declared in `pthread.h`
 - Not part of the C/C++ language
- To enable support for multithreading, must include `-pthread` flag when compiling and linking with `gcc` command
 - `gcc -g -Wall -std=c11 -pthread -o main main.c`

Creating and Terminating Threads

```
int pthread_create(  
    pthread_t* thread,  
    const pthread_attr_t* attr,  
    void* (*start_routine)(void*),  
    void* arg);
```

- Creates a new thread into `*thread`
- Returns **0** on success and an error number on error (can check against error constants)
- The new thread runs **start_routine**(arg)

```
void pthread_exit(void* retval);
```

- Equivalent of **exit**(retval); for a thread instead of a process
- The thread will automatically exit once it returns from **start_routine**()

What To Do After Spawning Threads?

```
int pthread_join(pthread_t thread, void** retval);
```

- Waits for the thread specified by `thread` to terminate
- The exit status of the terminated thread is placed in `*retval`

```
int pthread_detach(pthread_t thread);
```

- Mark thread specified by `thread` as detached – it will clean up its resources as soon as it terminates

Demo: cthreads

Concurrent Server with Threads

A single *process* handles all of the connections, but a parent *thread* dispatches (creates) a new thread to handle each connection

- The child thread handles the new connection and then exits when the connection terminates

Multithreaded Server

Multithreaded Server

Multithreaded Server

Multithreaded Server

Multithreaded Server

Why Concurrent Threads?

Advantages:

- Almost as simple to code as sequential
 - In fact, most of the code is identical! (but a bit more complicated to dispatch a thread)
- Concurrent execution with good CPU and network utilization
 - Some overhead, but less than processes
- Shared-memory communication is possible

Disadvantages:

- Synchronization is complicated
- Shared fate within a process
 - One “rogue” thread can hurt you badly

Questions?

Data Races

Data Races

Two memory accesses form a **data race** if different threads access the same location, and at least one is a write, and they occur one after another

- Means that the result of a program can vary depending on chance (which thread ran first?)

```
int x = 374;  
... // code that doesn't change x  
...  
...  
System.out.println(x);  
...  
...|  
x++;  
...  
...  
System.out.println(x);
```

Data Race Example

If your fridge has no milk,
then go out and buy some more

- What could go wrong?

If you live alone:

If you live with a roommate:

```
if (!milk) {  
  
    buy milk  
  
}
```

Polling Time!

Please answer in the LP23 assignment on Gradescope!

Idea: leave a note!

Does this fix the problem?

- **No**, could end up with no milk
- **No**, could still buy multiple milk
- **Yes**, problem fixed
- **Yes**, but it defeats the purpose of having multiple threads

```
if (!note) {  
    if (!milk) {  
        leave note  
        buy milk  
        remove note  
    }  
}
```

Poll Question Walkthrough

Alice	Bob
! note ! milk	
	! note ! milk Leave note Buy milk Remove note
Leave note Buy milk Remove note	

```
if (!note) {  
    if (!milk) {  
        leave note  
        buy milk  
        remove note  
    }  
}
```

Threads and Data Races

Data races might interfere in painful, non-obvious ways, depending on the specifics of the data structure

Example: two threads try to read from and write to the same shared memory location

- Could get “correct” answer
- Could accidentally read old value
- One thread’s work could get “lost”

Example: two threads try to push an item onto the head of the linked list at the same time

- Could get “correct” answer
- Could get different ordering of items
- Could break the data structure!

Synchronization

Synchronization is the act of preventing two (or more) concurrently running threads from interfering with each other when operating on shared data

- Need some mechanism to coordinate the threads
 - “Let me go first, then you can go”
- Many different coordination mechanisms have been invented

Goals of synchronization:

- **Liveness** – ability to execute in a timely manner
(informally, “something good happens”)
- **Safety** – avoid unintended interactions with shared data structures
(informally, “nothing bad happens”)

Lock Synchronization

Use a “Lock” to grant access to a **critical section** so that only one thread can operate there at a time

- Executed in an uninterruptible (*i.e.* **atomic**) manner

❖ Pseudocode:

Lock Acquire

- Wait until the lock is free, then take it

Lock Release

- Release the lock
- If other threads are waiting, wake exactly one up to pass lock to

```
// non-critical code
```

```
lock.acquire();
```

```
// critical section
```

```
lock.release();
```

```
// non-critical code
```

loop/idle
if locked

Milk Example – What is the Critical Section?

What if we use a lock on the refrigerator?

- Probably overkill – what if roommate wanted to get eggs?

For performance reasons, only put what is necessary in the critical section

- Only lock the milk
- But lock **all** steps that must run uninterrupted (*i.e.* must run as an atomic unit)

```
fridge.lock()  
if (!milk) {  
    buy milk  
}  
fridge.unlock()
```

```
milk_lock.lock()  
if (!milk) {  
    buy milk  
}  
milk_lock.unlock()
```

pthread and Locks

Another term for a lock is a **mutex** (“mutual exclusion”)

pthread.h defines datatype `pthread_mutex_t`

```
int pthread_mutex_init(pthread_mutex_t* mutex,  
                        const pthread_mutexattr_t* attr);
```

Initializes a mutex with specified attributes

```
int pthread_mutex_lock(pthread_mutex_t* mutex);
```

Acquire the lock – blocks if already locked

```
int pthread_mutex_unlock(pthread_mutex_t* mutex);
```

Releases the lock

```
int pthread_mutex_destroy(pthread_mutex_t* mutex);
```

“Uninitializes” a mutex – clean up when done

pthread Mutex Examples

See `total.cc`

- Data race between threads

See `total_locking.cc`

- Adding a mutex fixes our data race

How does this compare to sequential code?

- Likely *slower* – only 1 thread can increment at a time, but have to deal with checking the lock and switching between threads
- One possible fix: each thread increments a local variable and then adds its value (atomically) to the shared variable at the end

Demo: total and total_locking

C++11 Threads

C++11 added threads and concurrency to its libraries

- `<thread>` – thread objects
- `<mutex>` – locks to handle critical sections
- `<condition_variable>` – used to block objects until notified to resume
- `<atomic>` – indivisible, atomic operations
- `<future>` – asynchronous access to data
- These might be built on top of `<pthread.h>`, but also might not be

Definitely use in C++11 code if local conventions allow, but pthreads will be around for a long, long time

Questions?

Assignment Reminders

Exam 3 is on Friday, 10:50-12:50 in PCAR 291

- Use 26sp exam to study, disregard Misc. questions at the end
- Exam 3 grades will be released by Sunday night
- Regrade requests open until Monday night

HW 5 is due tonight, but late deadline has been extended to Sunday @ 11:59 PM

HW 6 (Extra Credit) can be submitted until Monday @ 11:59 PM

Bonus: Deadlock Game!
