

What is Computer Architecture?

Architecture

- the **interface** between the hardware & lowest levels of the software
 - **model** of the hardware
 - **contract** between the hardware & software
- instruction set architecture
 - instructions:
 - operations
 - operands, addressing the operands
 - how instructions are encoded
 - storage locations for data
 - registers: how many & what they are used for
 - memory: its size & how it is accessed
 - I/O devices & how to access them
 - software conventions:
 - subroutine calls: who saves the registers, which ones are saved
 - passing parameters: in registers? on the stack?

What is Computer Organization?

Microarchitecture (or Organization)

- basic components of a computer
 - on the CPU (ALU, registers, PC, etc.)
 - memory (levels of the cache hierarchy)
- how they operate
- how they are connected together

Organization is mostly invisible to the programmer

- today some components are considered **part of the architecture**
- why? because a programmer can get better performance if he/she knows the structure
- for example: the caches, the pipeline structure

Separate Architecture & its Organization

Why separate architecture & organization?

- many implementations for 1 architecture
 - **family** of implementations: sequences of machines that have the same ISA
 - MIPS R2000, R3000, R12000
 - Intel x86, Pentium series
 - IBM 360/85, 360/91, 370s
- ⇒ different points in the cost/performance curve
- ⇒ share software development costs
- ⇒ binary compatible: same software could run on all machines
- ⇒ open architecture: third party software

Different Architectures

So why have different architectures?

- different architecture philosophies & therefore different styles
 - support high level language operations: CISC
 - support basic primitive operations: RISC
- different application areas
 - *example*: multimedia instructions
- "ours is better" within the same style

Basic Architectural Design Principles

Design for the common case & make it fast

- common cases in hardware, uncommon cases in software
- make the common case hardware fast, even if it slows down the uncommon cases
- if a feature is not the common case, must have a good reason for adding it
- *examples:*
 - basic floating point operations in hardware
software function for the cosine routine
 - memory access in hardware
trap to software for a page fault

Why does this principle work?

- executing in hardware is faster than emulating in software
- **Amdahl's Law:** performance gain due to a hardware feature is limited by the fraction of time the feature is used

Basic Architectural Design Principles

Smaller is faster

- *examples:*
 - memory hierarchy: registers, caches, main memory
 - distributed rather than centralized designs

Keep it simple

- simplicity favors regularity, regularity leads to smaller designs and shorter design time
- *example:* RISC instructions are all 32 bits

Good design demands compromise

- trade-off in instruction format between
 - the size of the register file (how many bits are needed to specify a register) &
 - the number of operations (how many bits are needed to specify an instruction)
- trade-off between register size & cycle time

Assembly Language

Symbolic form of computer machine language

- advantages for us
 - learn at the machine level what a computer does
 - thorough understanding through a hands-on experience
 - easier for humans to understand than patterns of 1's & 0's

- where assembly language is used in practice
 - things that aren't expressible in a high-level language
for example: subroutine linkage
 - privileged tasks
for example: programs that need access to protected registers (I/O)
 - size-critical applications
for example: programs for embedded processors
 - time-critical applications
for example: real-time applications, OpenGL library

- why assembly language is not widely used
 - lower programmer productivity
for example: longer coding time, more debugging
 - compilers can produce almost the same quality code
 - not portable across architectures

Still Lower

Implementation

- design of organizational components or microarchitecture

Technology

- semiconductor material
for example: silicon
- circuit technology (how build gates from transistors)
for example: CMOS
- packaging
for example: pin-grid array
- generation
for example: vacuum tubes, VLSI
