Introducing caches Wouldn't it be nice if we could find a balance between CPU fast and cheap memory? We do this by introducing a cache, which is a small amount of fast, expensive memory. - The cache goes between the processor and the slower, dynamic main memory. A little static RAM (cache) - It keeps a copy of the most frequently used data from the main memory. Memory access speed increases overall, because we've made the common case faster. - Reads and writes to the most frequently used Lots of dynamic RAM addresses will be serviced by the cache. - We only need to access the slower main memory for less frequently used data.

## Other kinds of caches

- The general idea behind caches is used in many other situations.
- Networks are probably the best example.
  - Networks have relatively high "latency" and low "bandwidth," so repeated data transfers are undesirable.
  - Browsers like Netscape and Internet Explorer store your most recently accessed web pages on your hard disk.
  - Administrators can set up a network-wide cache, and companies like Akamai also provide caching services.
- A few other examples:
  - Many processors have a "translation lookaside buffer," which is a cache dedicated to virtual memory support.
  - Operating systems may store frequently-accessed disk blocks, like directories, in main memory... and that data may then in turn be stored in the CPU cache!
