

Evolution of ISA's

- ISA's have changed over computer "generations".
- A traditional way to look at ISA complexity encompasses:
 - Number of addresses per instruction
 - Regularity of instruction formats
 - Number of addressing types

Number of addresses per instruction

- First computer: 1 memory address + implied accumulator
- Then 1 memory address + “index” registers (for addressing operands)
- Followed by 1 memory address + “general registers” (for addressing and storing operands)
- Then 2 or 3 memory addresses + general registers
- Then N memory addresses + general registers (VAX)
- Also “0-address” computers, or “stack computers”
- In which category is MIPS, and more generally RISC machines?

Addresses per instruction

- RISC machines
 - Load-store and branches: 1 memory address + 2 registers
 - All other 3 registers or 2 registers + immediate
- CISC machines
 - Most of them: Two addresses
(destination ← source op. destination)
 - One operand is a register; other is either register, immediate, or given by memory address
 - Some special instructions (string manipulation) can have two memory addresses

Regularity of instruction formats

- Started with fixed format (ease of programming in “machine language”; few instructions)
- Then more flexibility (assembler/compiler): three or four instruction formats, not necessarily the same length
- Then strive for memory compactness. Complex, powerful, variable length instructions (x86)
- Back to regular instruction sets: few formats, instructions of the same length (memory is cheap; instructions must be decoded fast)

Number of instruction formats

- RISC: three or four (instructions have same length)
- CISC
 - Several formats, each of fixed (but maybe different) length
 - Variable length instructions (depends on opcode, addressing of operands etc. Intel x86 instructions from 1 to 17 bytes)
 - Instruction encoding via “specifiers”

Addressing modes

- In early machines: immediate, direct, indirect
- Then index registers
- Then index + base (sum of 2 registers instead of -- or in addition to -- index +displacement)
- All kinds of additional modes (indirect addressing, auto-increment, combinations of the above etc.)
- In general RISC
 - Immediate, indexed, and some time index + base (IBM Power PC)
- CISC
 - Anything goes...

The Ultimate CISC - VAX-11

- ISA defined late 70's. Last product mid 80's
- Over 200 instructions
 - Some very powerful: “polynomial evaluation”, procedure calls with register saving and frame set-up etc
- Complex addressing modes

A sample of VAX addressing modes

- Immediate (with even some small f-p constants)
- Direct (register) One instruction for each I-unit type
- Indirect (deferred)
- Autodecrement (and autoincrement) . The register is incremented by the I-unit type before (after) the operand is accessed
- Displacement (like MIPS indexed)
- Index like displacement but offset depends on the I-unit
- Combination of the above and more

Examples

- CLRL register (clears a whole register)
- CLRB register (clears the low byte of the register)
- CLRL (register) clears memory add whose add. is in reg.
- CLRL (register)+ as above but then register is incr. by 4
- CLRL @(register)+ as above with 1 more level of indirection (register points to address of address)
- CLRL offset(register) offset mult.by 4 for L, by 1 for B etc
- CLRL offset[register] similar but use offset + 4 * register
- CLRL 12(R4)+[R1] clear word at add. $R4 + 12*4 + R1*4$
and add 4 to R4

Intel x86: the largest number of CPU's in the world

- ISA defined early 80's
- Compatibility hurts:
 - 16 to 32-bit architecture
 - Paucity of general-purpose registers -- only 8
- Addressing relies on segments (code, data, stack)
- Lots of different instruction formats
- Lots of addressing modes (less than the Vax though)
- But ... over 300 millions CPU's in the world and growing
 - 85% of the market if you don't count embedded processors

X86 instruction encoding

- Opcode 1 or 2 bytes (defined by one bit in first byte)
- First byte following opcode is operand specifier
 - e.g., 2 registers
 - 1 register and the next byte specifies base and index register for a memory address for second operand and next byte specifies a displacement etc
 - etc.
- No regularity in instruction set

MIPS is not the only RISC

- MIPS family outgrowth of research at Stanford
- DEC (Compaq) Alpha has its roots in MIPS
- Sun family outgrowth of research at Berkeley
- IBM Power/PC family outgrowth of research at IBM
Watson
- HP Precision architecture
- more ...

Recent trends for high-end servers

- 32-bit architectures become 64-bit architectures
 - already in Dec Alpha, some HP-PA
- A “new” type of instruction format
 - VLIW (Very Long Instruction Word) or EPIC
 - Intel Merced (IA-64)
- More than one processor on a chip
- Embedded systems become “systems on a chip”

Current trends in RISC

- Not that “restricted”
 - instructions for MMX (multimedia)
 - instructions for multiprocessing (synchronization, memory hierarchy)
 - instructions for graphics
- Design is becoming more complex
- Execute several instructions at once (multiple ALU’s)
 - Speculative execution (guess branch outcomes)
 - Execute instructions out-of-order
- Ultimate goal is speed
