

# LL Parsing & Semantics

CSE 401/M501

Adapted from Spring 2021

# Announcements

- Parser + AST due **TONIGHT!**
- Homework 3 (LL grammars) due Monday
  - Only one late day, smaller assignment
  - Solutions released Wednesday to review for midterm
- Next section: midterm review
  - Bring your conceptual questions and past midterm questions!

13:00-14:00 OH (Mike) CSE2 131 + <a href="#">zoom</a>	25	16:00-17:00 OH (Dao) Allen 025 + <a href="#">zoom</a>	26	14:30-15:20 Lecture CSE2 G10 <i>Symbol tables and representation of types</i>	27	Section <i>LL parsing review; ASTs &amp; semantics</i>	28	13:30-14:30 OH (Wilson) CSE2 153 + <a href="#">zoom</a>	29

# Agenda

- **LL parsing worksheet**
- **Semantics & Type Checking**
  - **Review: Semantics vs. Type Checking**
  - **Type Checking for MiniJava**

# **Problem 1: LL parsing**

# **Semantics & Type Checking**

# Semantics, Dynamic and Static

***semantics***: precise meaning of program syntax

what interpretation or code generation implements

***dynamic semantics***: systematic rules to define runtime behavior

***static semantics***: systematic rules to define *statically correct* behavior

what type checking implements

# Static Semantics of MiniJava

Every language has its own idea of “statically correct,”  
but in MiniJava, statically correct code must...

1. *never* add, subtract, multiply, or print non-integers
2. *never* call a non-existent method
3. *never* access a non-existent field
- n.*** ... and so on (see the assignment page for more)

How do type checks relate to these conditions?

# Type Checking for MiniJava

The type checker's goal is to verify that a source program is statically correct.

We can't check that directly, but we can build a checkable type system so that:

***well-typed  $\Rightarrow$  statically correct***

Note: type checking depends on context – an implementation will depend on keeping track of types across different contexts (a scoped symbol table)

# Type Checking for MiniJava

# Examples

Suppose the following declarations are in effect:

*Global scope:* `class Foo { int f; int m(boolean b); }`

*Local scope:* `Foo this (implicit); int x; boolean y;`

In these scopes, which MiniJava expressions have type `int`? Why (not)?

`56`

`x+(new Foo()).f`

`x+this.m()`

`2+x`

`x+y`

`x+z.m(y)`

`this.f`

`(new Bar()).f`

`x+this.m(true)`

# Scopes and Symbol Tables

Accurately tracking scope information, via symbol tables, is critical to type checking.

## **Some guiding observations from today:**

- All classes in MiniJava will need symbol tables
  - When looking for a symbol, start in method table, then enclosing class, then global
- To generate symbol tables, it will make your life easier to go layer-by-layer
  - Global information needed everywhere! Makes sense to do that first
  - Easier to check a method body once global information is already computed
- Implementation tip:
  - Add pointers in your AST nodes to relevant type/symbol table information

# The Take-Away

Static semantics is usually about what code must **not** do.

- ∴ ruling out ill-behaved traces is a useful mental model
- ∴ implementing and debugging a type checker is all about **edge cases**
- ∴ need to consider all names in scope, with their type (signatures)

## **Problem 2: Static Semantics & Type Checking**
