Homework 5

The purpose of this homework is twofold:

1. Complete the detailed planning and design for the Lifecycle Architecture milestone.
2. Begin the construction phase of the project, resulting in an alpha release of the product.

This work will be presented as the Life Cycle Architecture milestone (LCA) along with a demo of the alpha release for your product in the LCA review on May 9th. Refer to the lectures on the LCA review and the construction phase of the project, as well as the various reference papers and web pages, for background material on the content of this review.

The homework is due before midnight, Thursday May 8th. One of the team members should turn in all the deliverables. On Friday, May 9th, there will be no class lecture. We will schedule 20-minute sessions throughout the day for LCA reviews with each team.

Deliverables

Much of the material for this review is an elaboration of the material that was written for the LCO reviews. Feel free to draw on that as a starting point. However, remember that you are defining the detailed architecture now, and so there should be fewer options and open items, and more decisions and detail.

1. An overview presentation. A set of Powerpoint presentation slides that summarizes the LCA elements for your product.

2. Specification document. This is the final version of the document that you produced earlier. It should accurately reflect the product you are building, from the point of view of both the client user and the server administrator.

3. Architecture document. Detailed definition of the system and software components. See the lectures and the attached extract from *Software Architecture* by Garlan for more information.

4. Task assignments. Task descriptions for the project and the specific team member responsible for each task. This is an update of the task list you provided earlier and should reflect your actual plan of work.

5. An alpha release of your client software, and an alpha release of your server software. This is a very early version of your product. It should illustrate the most important connectivity and functionality features, but is not expected to be the complete application. There should be four zip files total: one binary distribution and one source distribution for the client side and one binary distribution and one source distribution for the server side. There should be clearly identified release notes in each file describing how to install and run the software.

6. A demonstration of your application. This is a demonstration of the alpha release, not an additional turnin item. You will demonstrate your application in the LCA review on May 9th.
Architectural Description Languages. Extracted from Garlan.

The first insight is that good architectural description benefits from multiple views, each view capturing some aspect of the system. Two of the more important classes of view are:

- **Code-oriented views**, which describe how the software is organized into modules, and what kinds of implementation dependencies exist between those modules. Class diagrams, layered diagrams, and work breakdown structures are examples of this class of view; and
- **Execution-oriented views**, which describe how the system appears at run time, typically providing one or more snapshots of a system in action. These views are useful for documenting and analyzing execution properties such as performance, reliability, and security.

A second insight is that architectural description of execution-oriented views, as embodied in most of the ADLs mentioned earlier, requires the ability to model the following as first class design entities:

- **Components** represent the computational elements and data stores of a system. Intuitively, they correspond to the boxes in box-and-line descriptions of software architectures. Examples of components include clients, servers, filters, blackboards, and databases. Components may have multiple interfaces, each interface defining a point of interaction between a component and its environment. A component may have several interfaces of the same type (e.g., a server may have several active http connections).

- **Connectors** represent interactions among components. They provide the “glue” for architectural designs, and correspond to the lines in box-and-line descriptions. From a run-time perspective, connectors mediate the communication and coordination activities among components. Examples include simple forms of interaction, such as pipes, procedure call, and event broadcast. Connectors may also represent complex interactions, such as a client-server protocol or a SQL link between a database and an application. Connectors have interfaces that define the roles played by the participants in the interaction.

- **Systems** represent graphs of components and connectors. In general, systems may be hierarchical: components and connectors may represent subsystems that have their own internal architectures. We will refer to these as representations. When a system or part of a system has a representation, it is also necessary to explain the mapping between the internal and external interfaces.

- **Properties** represent additional information (beyond structure) about the parts of an architectural description. Although the properties that can be expressed by different ADLs vary considerably, typically they are used to represent anticipated or required extra-functional aspects of an architectural design. For example, some ADLs allow one to calculate system throughput and latency based on performance estimates of the constituent components and connectors. In general, it is desirable to be able to associate properties with any architectural element in a description (components, connectors, systems, and their interfaces). For example, a property of an interface might describe an interaction protocol.
