

Design patterns (part 3)

CSE 403
University of Washington

Michael Ernst

Outline

- ✓ Introduction to design patterns
- ✓ Creational patterns (constructing objects)
- ✓ Structural patterns (controlling heap layout)
 - ⇒ Behavioral patterns (affecting object semantics)

Review: Composite pattern

Composite permits a client to manipulate either an **atomic unit** or a **collection** of units in the same way

Good for dealing with part-whole relationships

Example behavior: traversing composites

- Goal: perform operations on all parts of a composite
- Idea: generalize the notion of an iterator

Composite example 1: Bicycle

- Bicycle
 - Frame
 - Drivetrain
 - Wheel
 - Tire
 - Tube
 - Tape
 - Rim
 - Nipples
 - Spokes
 - Hub
 - Skewer
 - Lever
 - Body
 - Cam
 - Rod
 - Acorn nut
 - ...

Methods on components

```
abstract class BicycleComponent {  
    int weight();  
    float cost();  
}  
  
class Wheel  
    extends BicycleComponent {  
    float assemblyCost;  
    Skewer skewer;  
    Hub hub;  
    ...  
    float cost() {  
        return assemblyCost  
            + skewer.cost()  
            + hub.cost()  
            + ...;  
    }  
}
```

```
class Bicycle  
    extends BicycleComponent {  
    float assemblyCost;  
    Frame frame;  
    Drivetrain drivetrain;  
    Wheel frontWheel;  
    ...  
    float cost() {  
        return assemblyCost  
            + frame.cost()  
            + drivetrain.cost()  
            + frontWheel.cost()  
            + ...;  
    }  
}
```

Composite example 2: Libraries

Library

 Section (for a given genre)

 Shelf

 Volume

 Page

 Column

 Word

 Letter

```
interface Text {
    String getText();
}

class Page implements Text {
    String getText() {
        ... return the concatenation of the column texts ...
    }
}
```

Composite example 3: Representing Java code

```
x = foo * 10 + c / d;
```

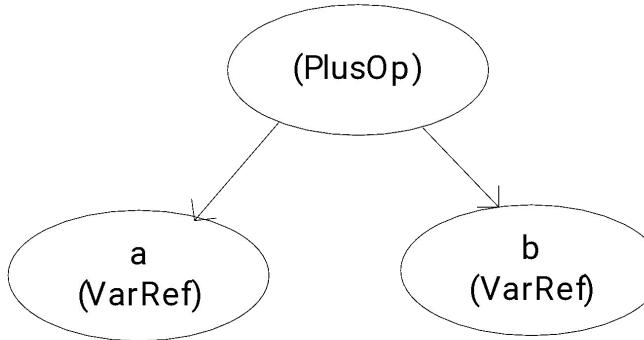

Abstract syntax tree (AST) for Java code

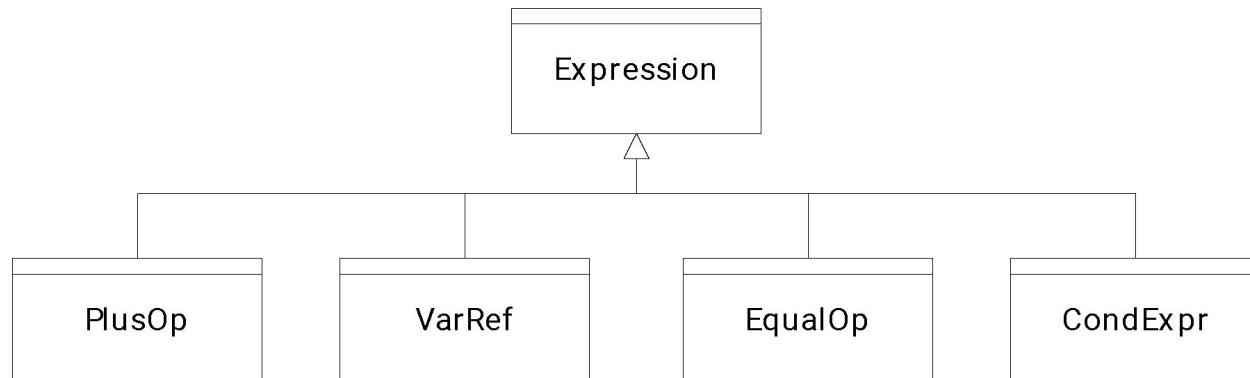

```
class PlusOp extends Expression {    // + operation
    Expression leftExp;
    Expression rightExp;
}
class VarRef extends Expression {    // variable reference
    String varname;
}
class EqualOp extends Expression {  // equality test a==b
    Expression lvalue;      // left-hand side: "a" in "a==b"
    Expression rvalue;      // right-hand side: "b" in "a==b"
}
class CondExpr extends Expression { // a?b:c
    Expression condition;
    Expression thenExpr;    // value of expression if a is true
    Expression elseExpr;   // value of expression if a is false
}
```

Object model (heap layout) vs. type hierarchy (subtyping)

- AST for "a + b":

- Class hierarchy for **Expression**:

Operations on Java expressions

Java expressions

- Plus: `20 + 22`
- Variable reference: `x`
- Method call: `foo(5)`
- Conditional: `b ? 3 : 4`
- Equals: `x == y`
- ...

Operations

- Typecheck
- Pretty-print
- Optimize
- ...

Type-checking an equality operation

```
// typecheck "a == b" where a and b are arbitrary
// expressions
Type tcEqualsOp(EqualOp e) {
    Type leftType = tcExpression(e.lvalue); // type of a
    Type rightType = tcExpression(e.rvalue); // type of b
    if (leftType != ERROR_TYPE
        && rightType != ERROR_TYPE
        && leftType == rightType) {
        return BOOLEAN_TYPE;
    } else {
        return ERROR_TYPE;
    }
}
```

Type-checking a conditional expr

```
// typecheck "a ? b : c"

Type tcCondExpr(CondExpr e) {
    Type condType = tcExpression(e.condition); // type of a
    Type thenType = tcExpression(e.thenExpr); // type of b
    Type elseType = tcExpression(e.elseExpr); // type of c
    if (condType != ERROR_TYPE
        && thenType != ERROR_TYPE
        && elseType != ERROR_TYPE
        && condType == BOOLEAN_TYPE
        && thenType == elseType) {
        return thenType;
    } else {
        return ERROR_TYPE;
    }
}
```

Organizing operations on abstract syntax trees

We know how to write code in each cell of this table:

		Objects	
		CondExpr	EqualOp
Operations	typecheck		
	pretty-print		

Question: Should we group together the code for a particular operation or the code for a particular expression?

(A separate issue: given an operation and an expression, how to select the proper piece of code to execute?)

Interpreter and procedural patterns

Interpreter: collects code for similar **objects**, spreads apart code for similar operations

Easy to add objects

Hard to add operations

An instance of the composite pattern

Procedural: collects code for similar **operations**, spreads apart code for similar objects

Easy to add operations

Hard to add objects

The visitor pattern is a variety of the procedural pattern

OO style

	Objects	
	CondExpr	EqualOp
typecheck		
pretty-print		

Functional style

	Objects	
	CondExpr	EqualOp
typecheck		
pretty-print		

Interpreter pattern

Objects	
CondExpr	
EqualOp	

Add a method to each class for each supported operation

```
class Expression {  
    ...  
    Type typecheck();  
    String prettyPrint();  
}
```

Dynamic dispatch chooses the right implementation, for a call like `myExpr.typeCheck()`

```
class EqualOp extends Expression { // "a == b"  
    ...  
    Type typecheck() { ... }  
    String prettyPrint() { ... }  
}
```

```
class CondExpr extends Expression { // "a?b:c"  
    ...  
    Type typecheck() { ... }  
    String prettyPrint() { ... }  
}
```

Procedural pattern

	CondExpr	EqualOp
typecheck		
pretty-print		

Create a class per operation, with a method per operand type

```

class Typecheck {
    // typecheck "a?b:c"
    Type tcCondExpr(CondExpr e) {
        Type condType = tcExpression(e.condition); // type of "a"
        Type thenType = tcExpression(e.thenExpr); // type of "b"
        Type elseType = tcExpression(e.elseExpr); // type of "c"
        if ((condType == BoolType) && (thenType == elseType)) {
            return thenType;
        } else {
            return ErrorType;
        }
    }

    // typecheck "a==b"
    Type tcEqualOp(EqualOp e) {
        ...
    }
}

```

Given an expression,
how to invoke the
right implementation?

Definition of tcExpression (in procedural pattern)

```
class Typecheck {  
    ...  
    Type tcExpression(Expression e) {  
        if (e instanceof PlusOp) {  
            return tcPlusOp((PlusOp)e);  
        } else if (e instanceof VarRef) {  
            return tcVarRef((VarRef)e);  
        } else if (e instanceof EqualOp) {  
            return tcEqualOp((EqualOp)e);  
        } else if (e instanceof CondExpr) {  
            return tcCondExpr((CondExpr)e);  
        } else ...  
        ...  
    }  
}
```

Maintaining this code is tedious and error-prone.
The cascaded if tests may run slowly.
Code duplication: this code is repeated in
PrettyPrint and every other operation class.
(Languages with pattern matching mitigate these
problems.)

Visitor pattern: a variant of the procedural pattern

Visitor encodes a traversal of a hierarchical data structure
Nodes (objects in the hierarchy) accept visitors
Visitors visit nodes (objects)

```
class SomeExpression extends Expression {  
    void accept(Visitor v) {  
        for each child of this node {  
            child.accept(v);  
        }  
        v.visit(this);  
    }  
}  
  
class SomeVisitor {  
    void visit(SomeExpression n) {  
        perform work on n  
    }  
    void visit(OtherExpression n) {  
        perform work on n  
    }  
}
```

n.accept(v) traverses the structure rooted at n, invoking v's operation

visit does the work on one element

What happened to all the instanceof operations?

Visitor pattern: example

Objects

```
class VarOp extends Expression {  
    void accept(Visitor v) {  
        v.visit(this);  
    }  
  
    class EqualsOp extends Expression {  
        void accept(Visitor v) {  
            leftExp.accept(v);  
            leftExp.accept(v);  
            v.visit(this);  
        }  
  
        class CondOp extends Expression {  
            void accept(Visitor v) {  
                testExp.accept(v);  
                thenExp.accept(v);  
                elseExp.accept(v);  
                v.visit(this);  
            }  
        }  
    }  
}
```

Operations

```
class TypeCheckVisitor implements Visitor {  
    void visit(EqualsOp e) {  
        assert e.leftExp and e.rightExp  
        have the same type  
    }  
    void visit(PlusOp e) {  
        assert e.leftExp and e.rightExp  
        are numeric  
    }  
}  
} Each operation has its cases  
together.  
Compiler error if a case is missing  
class PrettyPrintVisitor implements Visitor {  
    void visit(EqualsOp e) {  
        print e  
    }  
    void visit(PlusOp e) {  
        print e  
    }  
}
```

Visitor pattern: example

Objects

```
class VarOp extends Expression {  
    void accept(Visitor v) {  
        v.visit(this);  
    }  
  
class EqualsOp extends Expression {  
    void accept(Visitor v) {  
        leftExp.accept(v);  
        leftExp.accept(v);  
        v.visit(this);  
    }  
  
class CondOp extends Expression {  
    void accept(Visitor v) {  
        testExp.accept(v);  
        thenExp.accept(v);  
        elseExp.accept(v);  
        v.visit(this);  
    }  
}
```

Operations

```
class TypeCheckVisitor implements Visitor {  
    void visit(EqualsOp e) {  
        assert e.leftExp and e.rightExp  
        have the same type  
    }  
    void visit(PlusOp e) {  
        assert e.leftExp and e.rightExp  
        are numeric  
    }  
  
class PrettyPrintVisitor implements Visitor {  
    void visit(EqualsOp e) {  
        print e  
    }  
    void visit(PlusOp e) {  
        print e  
    }  
}
```

Overloading

Visitor pattern: example

Objects

```
class VarOp extends Expression {  
    void accept(Visitor v) {  
        v.visitVar(this);  
    }  
  
    class EqualsOp extends Expression {  
        void accept(Visitor v) {  
            leftExp.accept(v);  
            leftExp.accept(v);  
            v.visitEquals(this);  
        }  
  
        class CondOp extends Expression {  
            void accept(Visitor v) {  
                testExp.accept(v);  
                thenExp.accept(v);  
                elseExp.accept(v);  
                v.visitCond(this);  
            }  
        }
```

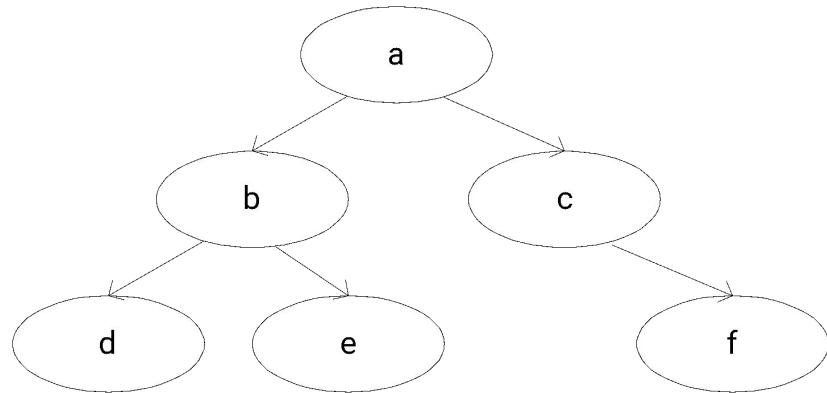

Operations

```
class TypeCheckVisitor implements Visitor {  
    void visitEquals(EqualsOp e) {  
        assert e.leftExp and e.rightExp  
        have the same type  
    }  
    void visitPlus(PlusOp e) {  
        assert e.leftExp and e.rightExp  
        are numeric  
    }  
  
    class PrettyPrintVisitor implements Visitor {  
        void visitEquals(EqualsOp e) {  
            print e  
        }  
        void visitPlus(PlusOp e) {  
            print e  
        }  
    }
```

Same behavior

Sequence of calls to accept and visit

a.accept(v)	
b.accept(v)	
d.accept(v)	d
v.visit(d)	
e.accept(v)	
v.visit(e)	e
v.visit(b)	b
c.accept(v)	
f.accept(v)	
v.visit(f)	f
v.visit(c)	c
v.visit(a)	a

Sequence of calls to visit = depth-first (children before parents)

How could we make it breadth-first (parents before children)?

Requires a different visitor

Visitors are like iterators

- Each element of the data structure is presented in turn to the `visit` method
- Visitors have knowledge of the structure, not just the sequence

Calls to `visit` cannot communicate with one another

1. Use an auxiliary data structure
2. `visit` returns a value
3. Move more work into the visitor itself

```
class Node {  
    void accept(Visitor v) {  
        v.visit(this);  
    }  
}  
class Visitor {  
    void visit(Node n) {  
        for each child of this node {  
            child.accept(v);  
        }  
        perform work on n  
    }  
}
```

Information flow is clearer (if visitor depends on children)
Traversal code repeated in all visitors (acceptor is extraneous)
