1

## Readings and References

- Reading
  - » Sections 3.7 through 3.8, *Computer Organization & Design*, Patterson and Hennessy
    - note error in figure page 149, address 80012 repeated

## Beyond Numbers

- Most computers today use 8-bit bytes to represent characters
- How many characters can you represent in an 8-bit byte?
  - » 256
- How many characters are needed to represent all the languages in the world?
  - » a gazillion, approximately

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

3

## char

- American Standard Code for Information Interchange (ASCII)
  - » published in 1968
  - » defines 7-bit character codes ...
  - » which means only the first 128 characters
  - » after that, it's all "extensions" and "code pages"
- ISO 8859-x
  - » codify the extensions to 8 bits (256 characters)

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

4

## ISO 8859-x

- Each “language” defines the extended chars
  - » Latin1 (West European) , Latin2 (East European), Latin3 (South European), Latin4 (North European), Cyrillic, Arabic, Greek, Hebrew, Latin5 (Turkish), Latin6 (Nordic)
  - » <http://www.microsoft.com/globaldev/reference/iso.mspx>
- How many languages are there?
  - » a gazillion, approximately

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

5

## Unicode

- Universal character encoding standard
  - » <http://www.unicode.org/>
- 16 bits should cover just about everything ...
  - » “original goal was to use a single 16-bit encoding that provides code points for more than 65,000 characters”
  - » the Java char type is a 16-bit character
- How many characters are needed? ...

9-Apr-2004

6

## Unicode does a million

Table 3-1. UTF-8 Bit Distribution

| Scalar Value      | UTF-16                                | 1st Byte              | 2nd Byte | 3rd Byte | 4th Byte |
|-------------------|---------------------------------------|-----------------------|----------|----------|----------|
| 00000000xxxxxx    | 00000000xxxxxx                        | 0xxxxxxx              |          |          |          |
| 00000yyyyyxxxxx   | 00000yyyyyxxxxx                       | 110yyyy               | 10xxxxxx |          |          |
| zzzzyyyyyxxxxxx   | zzzzyyyyyxxxxxx                       | 1110zzzz              | 10yyyyyy | 10xxxxxx |          |
| uuuuuzzzzyyyyyyyy | 110110wwwwzzzzyy+<br>110111yyyyxxxxxx | 11110uuu <sup>a</sup> | 10uuzzzz | 10yyyyyy | 10xxxxxx |

unicode scalar value:

a number N from 0 to  $10FFFF_{16}$  ( $1,114,111_{10}$ )

7

## Some character URLs

- ANSI X3.4 (ASCII)
  - » <http://czyborra.com/charsets/iso646.html>
- ISO 8859 (International extensions)
  - » <http://czyborra.com/charsets/iso8859.html>
- Unicode
  - » <http://www.unicode.org/>
  - » <http://www.unicode.org/iuc/iuc10/x-utf8.html>

czyborra.com seems to be offline right now ...

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

8

## Moving bytes

- A byte can contain an 8-bit character
- A byte can contain really small numbers  
0 to  $255_{10}$  or  $-128_{10}$  to  $127_{10}$
- Sign extension desired effect:
  - » sign bit not extended for characters
  - » sign bit extended for numbers

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

9

## Loading bytes

- Unsigned: **lbu \$reg, a(\$reg)**
  - » the byte is 0-extended into the register

|           |           |           |           |
|-----------|-----------|-----------|-----------|
| 0000 0000 | 0000 0000 | 0000 0000 | xxxx xxxx |
|-----------|-----------|-----------|-----------|

- Signed: **lb \$reg, a(\$reg)**
  - » bit 7 is extended through bit 31

|           |           |           |           |
|-----------|-----------|-----------|-----------|
| 0000 0000 | 0000 0000 | 0000 0000 | 0xxx xxxx |
|-----------|-----------|-----------|-----------|

|           |           |           |           |
|-----------|-----------|-----------|-----------|
| 1111 1111 | 1111 1111 | 1111 1111 | 1xxx xxxx |
|-----------|-----------|-----------|-----------|

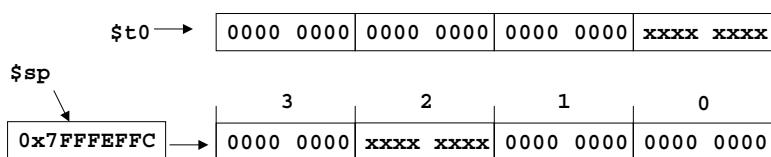

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

10

## Storing bytes

- No sign bit considerations
  - » the right most byte in the register is jammed into the byte address given
  - » **sb \$t0, 2(\$sp)**

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

11

## Storing strings

- Counted strings (for example Pascal strings)
  - » byte str[0] holds length: max 255 char
- Counted strings (for example Java strings)
  - » int variable holds length: max 2B char
- Terminated strings (for example C strings)
  - » no length variable, must count: max n/a

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

12

## strcpy example

```
char *strcpy(char *dst, const char *src) {  
    char *s = dst;  
    while ((*dst++ = *src++) != '\0')  
        ;  
    return s;  
}
```

Compared to example in the book:

- prototype matches libc
- pointers, not arrays
- better loop

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

13

## strcpy compiled

```
strcpy:  
    move    $v1,$a0          # remember initial dst  
loop:  
    lbu     $v0,0($a1)       # load a byte  
    sb      $v0,0($a0)       # store it  
    sll     $v0,$v0,24       # toss the extra bytes  
    addu   $a1,$a1,1         # src++  
    addu   $a0,$a0,1         # dst++  
    bne    $v0,$zero,loop    # loop if not done  
    move   $v0,$v1           # return initial dst  
    j      $ra               # return
```

9-Apr-2004

14

## Manipulating the bits

- Shift Logical
  - » sll, srl, sllv, sriv - shift bits in word, 0-extend
  - » use these to isolate bits in a word
  - » shift amount in instruction or in register
- Bit by bit
  - » and, andi - clear bits in destination
  - » or, ori - set bits in destination

Shift to the left, shift to the right, push down, pop up, byte, byte, byte!

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

15

## Example: bit manipulation

```
sll  $t1,$t1,24  
0000 0000 0000 0000 0000 1111 1010 1111  
1010 1111 0000 0000 0000 0000 0000 0000  
  
srl  $t1,$t1,28  
1010 1111 0000 0000 0000 0000 0000 0000  
0000 0000 0000 0000 0000 0000 0000 1010  
  
ori  $t1,$t1,0x100  
0000 0000 0000 0000 0000 0000 0000 1010  
0000 0000 0000 0000 0000 0001 0000 1010
```

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

16

## Example: C bit fields

- Example in the book on page 229 is a typical application of bit fields

- But, note poor choice of field locations
  - » the received byte is not aligned
  - » the byte must be shifted before it can be used
- To: EE designers of interfaces
  - » please consider alignment when selecting fields

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

17

## Multiply and Divide

- There is a separate integer multiply unit
- Use pseudo-instructions to access
  - `mul $t0,$t1,$t2 # t0 = t1*t2`
  - `div $t0,$t1,$t2 # t0 = t1/t2`
- These are relatively slow
  - » multiply 5-12 clock cycles
  - » divide 35-80 clock cycles

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

18

## Addressing modes

- Register              `jr $ra`
- Offset + Register    `lw $t0,0($sp)`
- Immediate            `addi $t0,17`
- PC relative          `bnez $t0,loop`
- Pseudodirect         `jal proc`

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

19

## Register only

- Use the 32 bits of the specified register as the desired address
- Can specify anywhere in the program address space, without limitation
- `jr $ra`
  - » return to caller after procedure completes

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

20

## Offset + Register

- Specify 16-bit signed offset to add to the base register
- Transfer (lw, sw) base register is specified
  - » **lw \$t0,4(\$sp)**
  - » **sw \$t0,40(\$gp)**

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

21

## Immediate

- The 16-bit field holds the constant value

```
0x34080001 ori $8, $0, 1      ; 4: li $t0,1
0x3c01ffff lui $1, -1        ; 5: li $t0,-1
0x3428ffff ori $8, $1, -1    ; 6: li $t0,0xFFFF
0x3408ffff ori $8, $0, -1    ; 7: li $t0,0x1FFFF
0x3c010001 lui $1, 1         ; 8: li $t0,0x5555AAAA
0x3428ffff ori $8, $1, -1    ; 9: la $t0,main
0x3c015555 lui $1, 21845     ; 10: la $t0,main
0x3428aaaa ori $8, $1, -21846
0x3c010040 lui $1, 64 [main] ; 11: la $t0,main
0x34280020 ori $8, $1, 32 [main]
```

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

22

## PC relative

- Branch (beq, bne) base register is PC
  - » **beq \$t0,\$t1,skip**
- The 16-bit value stored in the instruction is considered to be a word offset
  - » multiplied by 4 before adding to PC
  - » can branch over  $\pm 32\text{ K}$  instruction range

9-Apr-2004

cse410-07-addressing © 2004 University of Washington

23

## Pseudodirect

- The specified offset is 26 bits long
  - » Considered to be a word offset
  - » multiplied by 4 before use
- The top 4 bits of the PC are concatenated with the new 28 bit offset to give a 32-bit address
- Can jump within 256 MB segment
