

# Scheduling (Win 2K)

CSE 410, Spring 2004  
Computer Systems

<http://www.cs.washington.edu/education/courses/410/04sp/>

# Readings and References

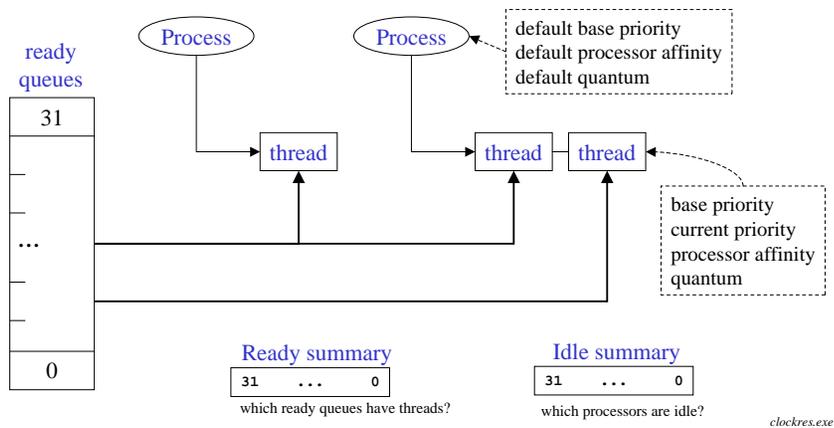

- Reading

- » Chapter 6, Section 6.7.2, *Operating System Concepts*, Silberschatz, Galvin, and Gagne

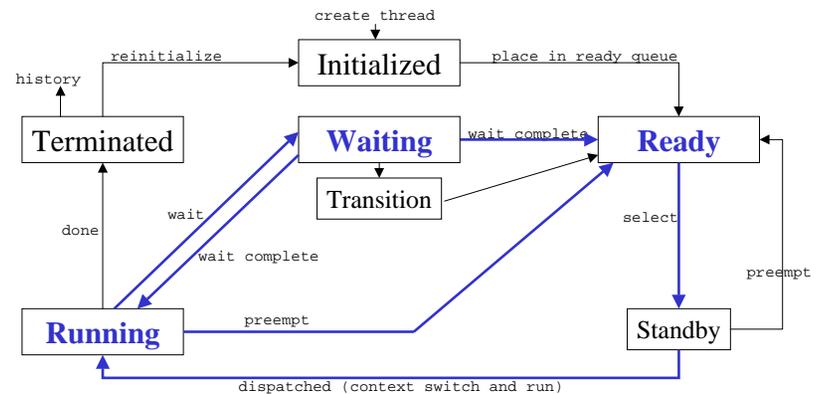

- Other References

- » Chapter 6, Section “Thread Scheduling”, *Inside Microsoft Windows 2000*, Third Edition, Solomon and Russinovich. This book is the source of most of today’s lecture.
- » Chapter 6, Performance Monitoring, *Windows 2000 Professional Resource Kit*, Microsoft

# Dispatcher “database”

# Thread State Transitions

## Ready, Running, Waiting

- Ready
  - » ready to run if there is a processor available
  - » there is a ready queue for each priority level
- Running
  - » has been switched to and is running
- Waiting
  - » waiting on an event (synchronize, I/O, etc)

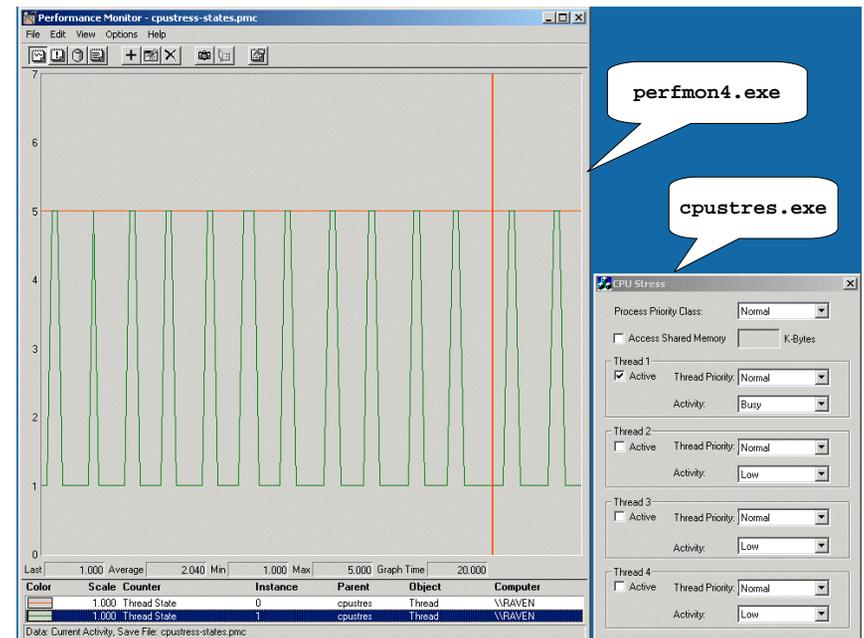

## Other States

- Initialized
  - » On its way in the door
- Terminated
  - » On its way out the door to history or recycle
- Standby
  - » Ready and selected to run next
- Transition
  - » Ready, but important parts are paged out

## Windows 2000 Thread States

- 7 - Unknown
- 6 - Transition
- 5 - Wait (for something to complete)
- 4 - Terminated
- 3 - Standby (on-deck circle)
- 2 - Running (at bat)
- 1 - Ready (eligible to be selected)
- 0 - Initialized

ThreadStatesX1.msc

## Setting Thread Priorities

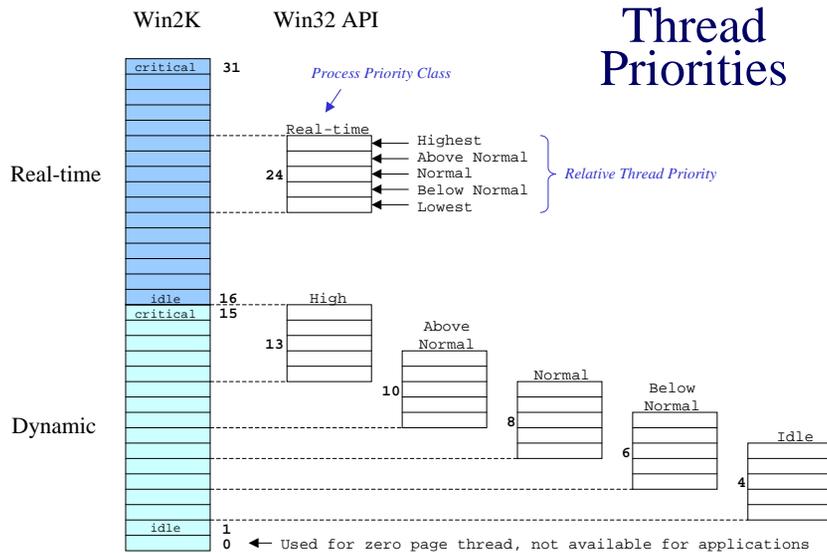

- Base priority
  - » normally inherited from process default
  - » can be explicitly set
- Current priority
  - » starts out same as base
  - » real time never changes
  - » dynamic is boosted when appropriate for responsiveness

## Thread Priorities

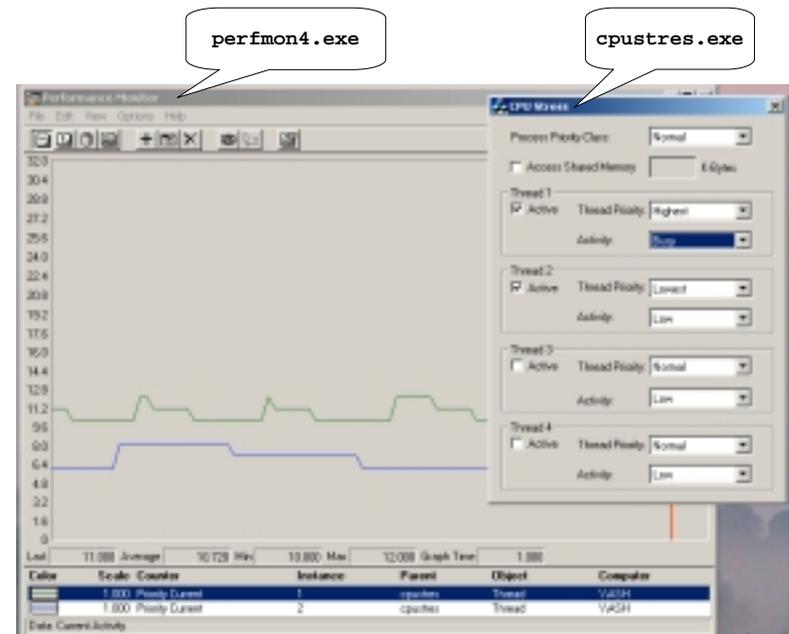

## Priority boosting

- After I/O completion or event wait
  - » you've waited for this data, now use it quick
- User response
  - » Foreground thread after a wait or window thread wakeup for window event
- CPU starvation
  - » found an aging thread on the ready queues
- The boost decays quickly over time

## Quantum

---

- Thread Quantum is
  - » indicator of the amount of time a thread can run before W2K checks whether another thread at the same priority should get to run
- Each thread has a current quantum value
  - » a small integer that is decremented under various circumstances
  - » not an actual length of time, just a number

## Quantum value

---

- Thread quantum is initialized when thread is put on the ready queue
  - » initial value of 6 on Windows 2K Professional
  - » initial value of 36 on Windows 2K Server
- Quantum of running thread is decremented by 3 after system clock interrupt
  - » so a W2K Pro thread can run for 2 clock intervals
  - » a W2K Server thread can run for 12 clock intervals

## Quantum is reset to initial value

---

- a thread moves to ready queue after quantum end
  - » in other words, a thread is given another chunk of time to use after it has exhausted the first chunk
- a real-time thread is preempted and moves from running to ready or it moves from running to wait
  - » the presumption is that you are doing a good job of explicitly managing priorities and access to the CPU when you are running real-time threads

## Quantum changes

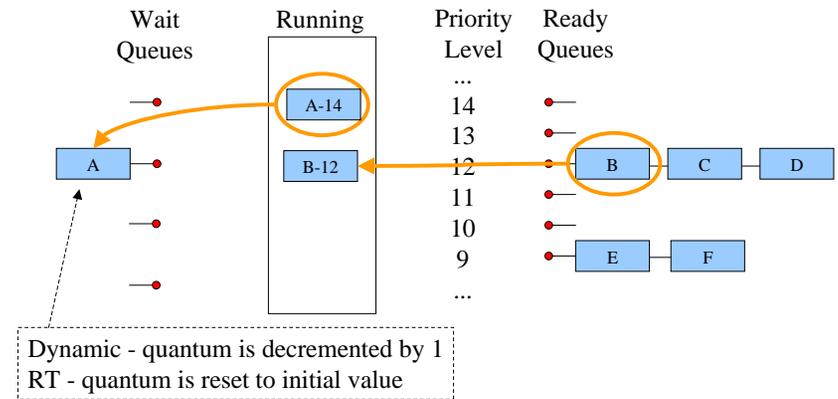

---

- Quantum is decremented
  - » reduced quantum => less time remaining before thread has exhausted its time slice
  - » reduced by 3 when the clock ticks
  - » by 1 when dynamic thread executes a wait
- Quantum initial value may be boosted
  - » “Optimize performance for applications”
  - => boost initial quantum for foreground threads

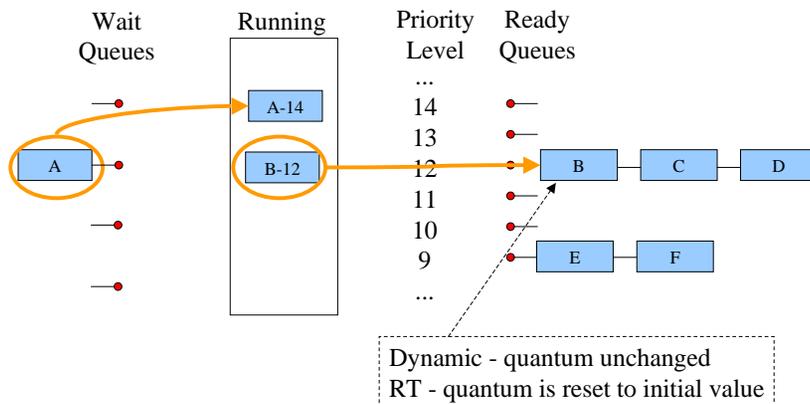

# Scheduling Scenarios

- Voluntary switch
  - » thread calls a wait function of some sort
- Preemption
  - » higher priority thread is ready to run
- Quantum end
  - » the running thread exhausts its quantum

# Voluntary Switch

# Preemption

# Quantum End
