

# Assembly Programming II

CSE 410 Winter 2017

**Instructor:**

Justin Hsia

**Teaching Assistants:**

Kathryn Chan, Kevin Bi, Ryan Wong, Waylon Huang, Xinyu Sui

# Administrivia

- ❖ Lab 1 due tomorrow (1/26)
  - You have *late days* available
- ❖ Lab 2 (x86-64) released on Friday (1/27)
- ❖ Homework 2 due next Tuesday (1/31)
  
- ❖ Optional Section this Thursday
  - Floating Point and GDB (The GNU Debugger)
  - Recommended to bring your laptop
  
- ❖ Thursday OH moved to 10:30am
  - Kathryn & Xinyu, CSE 2<sup>nd</sup> floor breakout

# x86-64 Introduction

- ❖ Arithmetic operations
- ❖ Memory addressing modes
  - `swap` example
- ❖ Address computation instruction (`leaq`)

# Review: Operand types

- ❖ **Immediate:** Constant integer data
  - Examples: `$0x400`, `$-533`
  - Like C literal, but prefixed with ``$'`
  - Encoded with 1, 2, 4, or 8 bytes *depending on the instruction*
- ❖ **Register:** 1 of 16 integer registers
  - Examples: `%rax`, `%r13`
  - But `%rsp` reserved for special use
  - Others have special uses for particular instructions
- ❖ **Memory:** Consecutive bytes of memory at a computed address
  - Simplest example: `(%rax)`
  - Various other “address modes”

`%rax``%rcx``%rdx``%rbx``%rsi``%rdi``%rsp``%rbp``%rN`

# Some Arithmetic Operations

## ❖ Binary (two-operand) Instructions:

■ **Maximum of one memory operand**

■ Beware argument order!

■ No distinction between signed and unsigned

- Only arithmetic vs. logical shifts

■ How do you implement “ $r3 = r1 + r2$ ”?

Format	Computation	
<code>addq src, dst</code>	$dst = dst + src$	( $dst += src$ )
<code>subq src, dst</code>	$dst = dst - src$	
<code>imulq src, dst</code>	$dst = dst * src$	signed mult
<code>sarq src, dst</code>	$dst = dst \gg src$	Arithmetic
<code>shrq src, dst</code>	$dst = dst \gg src$	Logical
<code>shlq src, dst</code>	$dst = dst \ll src$	(same as <code>salq</code> )
<code>xorq src, dst</code>	$dst = dst \wedge src$	
<code>andq src, dst</code>	$dst = dst \& src$	
<code>orq src, dst</code>	$dst = dst   src$	

↑ operand size specifier

# Some Arithmetic Operations

## ❖ Unary (one-operand) Instructions:

Format	Computation	
<code>incq dst</code>	$dst = dst + 1$	increment
<code>decq dst</code>	$dst = dst - 1$	decrement
<code>negq dst</code>	$dst = -dst$	negate
<code>notq dst</code>	$dst = \sim dst$	bitwise complement

## ❖ See CSPP Section 3.5.5 for more instructions: `mulq`, `cqto`, `idivq`, `divq`

# Arithmetic Example

Register	Use(s)
%rdi	1 <sup>st</sup> argument (x)
%rsi	2 <sup>nd</sup> argument (y)
%rax	return value

```

long simple_arith(long x, long y)
{
    long t1 = x + y;
    long t2 = t1 * 3;
    return t2;
}
    
```

```

y += x;
y *= 3;
long r = y;
return r;
    
```

```

simple_arith:
    addq    %rdi, %rsi
    imulq   $3, %rsi
    movq    %rsi, %rax
    ret
    
```

# Example of Basic Addressing Modes

```
void swap(long *xp, long *yp)
{
    long t0 = *xp;
    long t1 = *yp;
    *xp = t1;
    *yp = t0;
}
```

```
swap:
    movq    (%rdi), %rax
    movq    (%rsi), %rdx
    movq    %rdx, (%rdi)
    movq    %rax, (%rsi)
    ret
```

# Understanding swap ( )

```
void swap(long *xp, long *yp)
{
    long t0 = *xp;
    long t1 = *yp;
    *xp = t1;
    *yp = t0;
}
```

```
swap:
    movq    (%rdi), %rax
    movq    (%rsi), %rdx
    movq    %rdx, (%rdi)
    movq    %rax, (%rsi)
    ret
```

<u>Register</u>		<u>Variable</u>
%rdi	↔	xp
%rsi	↔	yp
%rax	↔	t0
%rdx	↔	t1

# Understanding swap( )

## Registers

%rdi	0x120
%rsi	0x100
%rax	
%rdx	

## Memory Word Address

123	0x120
	0x118
	0x110
	0x108
456	0x100

```
swap:
```

```
    movq    (%rdi), %rax    # t0 = *xp
    movq    (%rsi), %rdx    # t1 = *yp
    movq    %rdx, (%rdi)    # *xp = t1
    movq    %rax, (%rsi)    # *yp = t0
    ret
```

# Understanding swap( )

```
swap:
```

```
    movq    (%rdi), %rax    # t0 = *xp
    movq    (%rsi), %rdx    # t1 = *yp
    movq    %rdx, (%rdi)    # *xp = t1
    movq    %rax, (%rsi)    # *yp = t0
    ret
```

# Understanding swap( )

```
swap:
```

```
    movq    (%rdi), %rax    # t0 = *xp  
    movq   (%rsi), %rdx    # t1 = *yp  
    movq   %rdx, (%rdi)    # *xp = t1  
    movq   %rax, (%rsi)    # *yp = t0  
    ret
```

# Understanding swap ( )

```

swap:
    movq    (%rdi), %rax    # t0 = *xp
    movq    (%rsi), %rdx    # t1 = *yp
    movq    %rdx, (%rdi)    # *xp = t1
    movq    %rax, (%rsi)    # *yp = t0
    ret
    
```

# Understanding swap( )

```
swap:
```

```
    movq    (%rdi), %rax    # t0 = *xp  
    movq    (%rsi), %rdx    # t1 = *yp  
    movq    %rdx, (%rdi)    # *xp = t1  
    movq    %rax, (%rsi)    # *yp = t0  
    ret
```

# Memory Addressing Modes: Basic

❖ **Indirect:**  $(R)$   $\text{Mem}[\text{Reg}[R]]$

- Data in register  $R$  specifies the memory address
- Like pointer dereference in C
- Example: `movq (%rcx), %rax`

❖ **Displacement:**  $D(R)$   $\text{Mem}[\text{Reg}[R]+D]$

- Data in register  $R$  specifies the *start* of some memory region
- Constant displacement  $D$  specifies the offset from that address
- Example: `movq 8(%rbp), %rdx`

# Complete Memory Addressing Modes

## ❖ General:

- $D(Rb, Ri, S)$      $Mem[Reg[Rb]+Reg[Ri]*S+D]$ 
  - Rb:     Base register (any register)
  - Ri:     Index register (any register except %rsp)
  - S:     Scale factor (1, 2, 4, 8) – *why these numbers?*
  - D:     Constant displacement value (a.k.a. immediate)

## ❖ Special cases (see CSPP Figure 3.3 on p.181)

- $D(Rb, Ri)$              $Mem[Reg[Rb]+Reg[Ri]+D]$     ( $S=1$ )
- $(Rb, Ri, S)$          $Mem[Reg[Rb]+Reg[Ri]*S]$     ( $D=0$ )
- $(Rb, Ri)$              $Mem[Reg[Rb]+Reg[Ri]]$         ( $S=1, D=0$ )
- $(, Ri, S)$              $Mem[Reg[Ri]*S]$                 ( $Rb=0, D=0$ )

# Address Computation Examples

<code>%rdx</code>	<code>0xf000</code>
<code>%rcx</code>	<code>0x0100</code>

$$D(Rb, Ri, S) \rightarrow \text{Mem}[\text{Reg}[Rb] + \text{Reg}[Ri] * S + D]$$

Expression	Address Computation	Address
<code>0x8(%rdx)</code>		
<code>(%rdx,%rcx)</code>		
<code>(%rdx,%rcx,4)</code>		
<code>0x80(,%rdx,2)</code>		

# Address Computation Instruction

- ❖ `leaq src, dst`
  - “lea” stands for *load effective address*
  - `src` is address expression (any of the formats we’ve seen)
  - `dst` is a register
  - Sets `dst` to the *address* computed by the `src` expression (**does not go to memory! – it just does math**)
  - Example: `leaq (%rdx,%rcx,4), %rax`
- ❖ Uses:
  - Computing addresses without a memory reference
    - e.g. translation of `p = &x[i];`
  - Computing arithmetic expressions of the form  $x+k*i+d$ 
    - Though `k` can only be 1, 2, 4, or 8

# Example: lea vs. mov

## Registers

%rax	
%rbx	
%rcx	0x4
%rdx	0x100
%rdi	
%rsi	

## Memory

	Word Address
0x400	0x120
0xF	0x118
0x8	0x110
0x10	0x108
0x1	0x100

```
leaq (%rdx,%rcx,4), %rax
movq (%rdx,%rcx,4), %rbx
leaq (%rdx), %rdi
movq (%rdx), %rsi
```

# Arithmetic Example

```
long arith(long x, long y, long z)
{
    long t1 = x + y;
    long t2 = z + t1;
    long t3 = x + 4;
    long t4 = y * 48;
    long t5 = t3 + t4;
    long rval = t2 * t5;
    return rval;
}
```

```
arith:
    leaq    (%rdi,%rsi), %rax
    addq   %rdx, %rax
    leaq   (%rsi,%rsi,2), %rdx
    salq  $4, %rdx
    leaq  4(%rdi,%rdx), %rcx
    imulq %rcx, %rax
    ret
```

Register	Use(s)
%rdi	1 <sup>st</sup> argument (x)
%rsi	2 <sup>nd</sup> argument (y)
%rdx	3 <sup>rd</sup> argument (z)

- ❖ Interesting Instructions
  - leaq: “address” computation
  - salq: shift
  - imulq: multiplication
    - Only used once!

# Arithmetic Example

```

long arith(long x, long y, long z)
{
    long t1 = x + y;
    long t2 = z + t1;
    long t3 = x + 4;
    long t4 = y * 48;
    long t5 = t3 + t4;
    long rval = t2 * t5;
    return rval;
}

```

Register	Use(s)
%rdi	x
%rsi	y
%rdx	z, t4
%rax	t1, t2, rval
%rcx	t5

```

arith:
    leaq    (%rdi,%rsi), %rax    # rax/t1    = x + y
    addq   %rdx, %rax          # rax/t2    = t1 + z
    leaq   (%rsi,%rsi,2), %rdx  # rdx       = 3 * y
    salq   $4, %rdx           # rdx/t4    = (3*y) * 16
    leaq   4(%rdi,%rdx), %rcx  # rcx/t5    = x + t4 + 4
    imulq  %rcx, %rax         # rax/rval  = t5 * t2
    ret

```

# Peer Instruction Question

❖ Which of the following x86-64 instructions correctly calculates `%rax=9*%rdi`?

▪ Vote at <http://PollEv.com/justinh>

A. `leaq (,%rdi,9), %rax`

B. `movq (,%rdi,9), %rax`

C. `leaq (%rdi,%rdi,8), %rax`

D. `movq (%rdi,%rdi,8), %rax`

E. We're lost...

# x86 Control Flow

- ❖ Condition codes
- ❖ Conditional and unconditional branches
- ❖ Loops
- ❖ Switches

# Control Flow

Register	Use(s)
%rdi	1 <sup>st</sup> argument (x)
%rsi	2 <sup>nd</sup> argument (y)
%rax	return value

```
long max(long x, long y)
{
    long max;
    if (x > y) {
        max = x;
    } else {
        max = y;
    }
    return max;
}
```

```
max:
    ???
    movq    %rdi, %rax
    ???
    ???
    movq    %rsi, %rax
    ???
    ret
```

# Control Flow

Register	Use(s)
%rdi	1 <sup>st</sup> argument (x)
%rsi	2 <sup>nd</sup> argument (y)
%rax	return value

```

long max(long x, long y)
{
    long max;
    if (x > y) {
        max = x;
    } else {
        max = y;
    }
    return max;
}
    
```

**Conditional jump** →

**Unconditional jump** →

```

max:
    if x <= y then jump to else
    movq    %rdi, %rax
    jump   to done
else:
    movq    %rsi, %rax
done:
    ret
    
```

# Conditionals and Control Flow

- ❖ Conditional branch/*jump*
  - Jump to somewhere else if some *condition* is true, otherwise execute next instruction
- ❖ Unconditional branch/*jump*
  - *Always* jump when you get to this instruction
- ❖ Together, they can implement most control flow constructs in high-level languages:
  - `if (condition) then {...} else {...}`
  - `while (condition) {...}`
  - `do {...} while (condition)`
  - `for (initialization; condition; iterative) {...}`
  - `switch {...}`

# Summary

- ❖ **Memory Addressing Modes:** The addresses used for accessing memory in `mov` (and other) instructions can be computed in several different ways
  - *Base register, index register, scale factor, and displacement* map well to pointer arithmetic operations
- ❖ `lea` is address calculation instruction
  - Does NOT actually go to memory
  - Used to compute addresses or some arithmetic expressions
- ❖ Control flow in x86 determined by status of Condition Codes
