Abstraction is a good thing

- The span of absolute judgment and the span of immediate memory impose severe limitations on the amount of information that we are able to receive, process, and remember.
- By organizing the stimulus input simultaneously into several dimensions and successively into a sequence or chunks, we manage to break (or at least stretch) this informational bottleneck.
 - » Miller, 1956. see OtherLinks page for reference

A clean abstraction is a good thing

- How to chop up the system in a "logical" way?
- "Common sense" design is not always obvious
- Key issues: cohesion & coupling

Cohesion and Coupling

- Cohesion describes the degree to which the various parts of a single conceptual object relate to one another in a logical way
- Coupling describes the degree to which different conceptual objects are tied together through implementation details and assumptions

Name space pollution

- One common problem that contributes to coupling between modules is naming
- As much as possible, you want to keep the details of your implementation from leaking out into the outside world. Why?

Procedure names

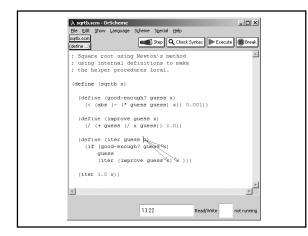

- Recall that sqrta.scm defined a number of small auxiliary procedures to accomplish the task of calculating the square root
 - » sqrt-iter, good-enough?, improve
- None of these procedures are of specific interest to the outside world
 - » they interfere with other designs that want to build other procedures with the same names
 - » the prefix "sqrt-" is clutter in our own design

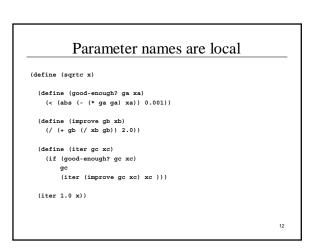

Helper definitions local to procedure (define (sqrtb x) :Square root using Newton's method (define (good-enough? guess x) :the helper procedures local. (< (abs (- (* guess guess) x)) 0.001))</td> (define (improve guess x) (/ (+ guess (/ x guess)) 2.0)) (define (iter guess x) (if (good-enough? guess x) (if (good-enough? guess x) (iter (improve guess x) x))) (iter (inprove guess x) x)))

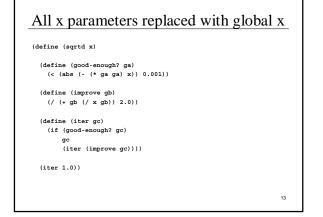

Local names

- The names of the helper procedures are now local to the define statement for sqrt
- The scope of the names is the define block
- Notice that the scope of the names of the formal parameters of each local procedure is the body of that procedure
 - » the parameter names of a procedure are local to the body of the procedure

10

Lexical scoping

- The preceding changes to the sqrt definition are examples of the use of *lexical scoping*
- Free variables (those that are not bound by the parameter list or a local define) are taken to refer to bindings made by enclosing procedure definitions
- The bindings are looked up in the environment in which the procedure was...

14

16

Recursion and Iteration

- Definitions
 - » procedure (the text definition)
 - » process (the actual live action events)
- A recursive procedure (one that calls itself) does not necessarily generate a recursive process (one that has an open deferred operations remaining for each call)

Two implementations of factorial

; linear recursive

(define (facta n) (if (= n 1) 1

```
(* n (facta (- n 1)))))
```

; iterative

15

(define (factb n) (define (iter prod count) (if (> count n) prod (iter (* count prod) (+ count 1)))) (iter 1))

Difference • The key difference between the linear recursive process and the iterative process is
