# Generic linear regression model

Model:

$$y_i = w_0 h_0(x_i) + w_1 h_1(x_i) + \dots + w_D h_D(x_i) + \varepsilon_i$$
$$= \sum_{j=0}^D w_j h_j(x_i) + \varepsilon_i$$

*feature 1* =  $h_0(x)$  ... e.g., 1

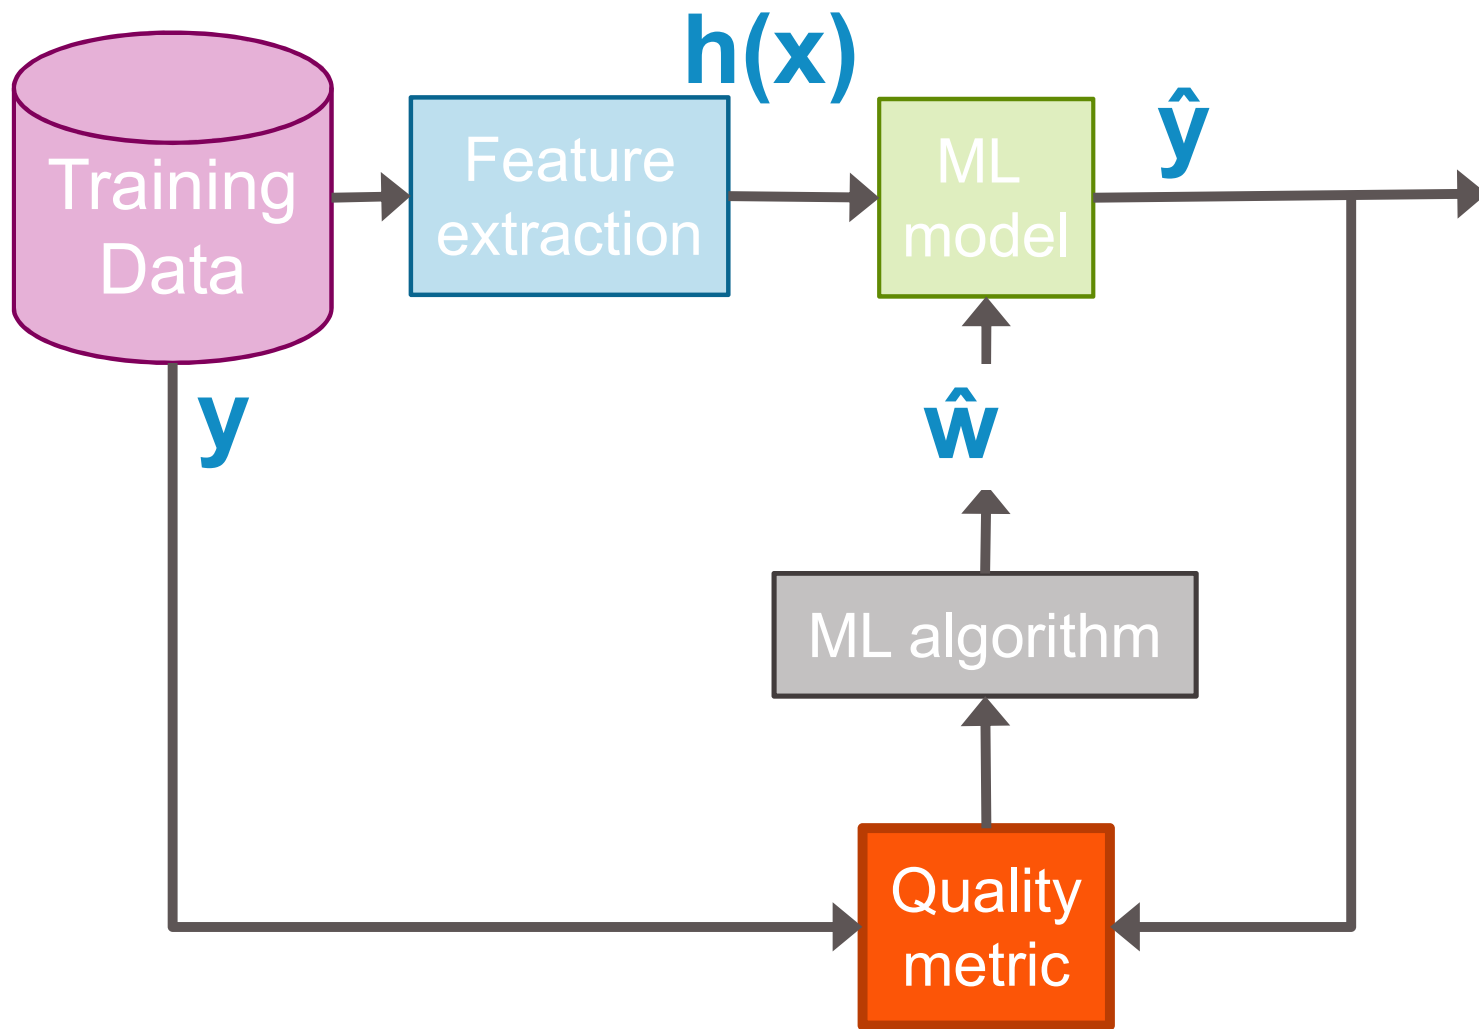

*feature 2* =  $h_1(x)$  ... e.g.,  $x[1]$  = sq. ft.

*feature 3* =  $h_2(x)$  ... e.g.,  $x[2]$  = #bath

or,  $\log(x[7])$   $x[2]$  =  $\log(\text{\#bed})$  x #bath

...

*feature D+1* =  $h_D(x)$  ... some other function of  $x[1], \dots, x[d]$

# Measuring loss

Loss function:

Cost of using  $\hat{w}$  at  $x$   
when  $y$  is true

$$L(y, \underbrace{f_{\hat{w}}(x)}_{\hat{f}(x) = \text{predicted value } \hat{y}})$$

actual value

Examples: (assuming loss for underpredicting = overpredicting)

Absolute error:  $L(y, f_{\hat{w}}(x)) = |y - f_{\hat{w}}(x)|$

Squared error:  $L(y, f_{\hat{w}}(x)) = (y - f_{\hat{w}}(x))^2$

# Fit data with a line or ... ?

©2018 Emily Fox

Dude, it's not a linear relationship!

# What about a quadratic function?

©2018 Emily Fox

Dude, it's not a linear relationship!

# Even higher order polynomial

I can minimize your RSS

# Assessing the loss

## Part 1: Training error

# Define training data

# Define training data

# Example: Fit quadratic to minimize RSS

# Compute training error

1. Define a loss function  $L(y, f_{\hat{w}}(x))$

- E.g., squared error, absolute error, ...

2. Training error

= avg. loss on houses in training set

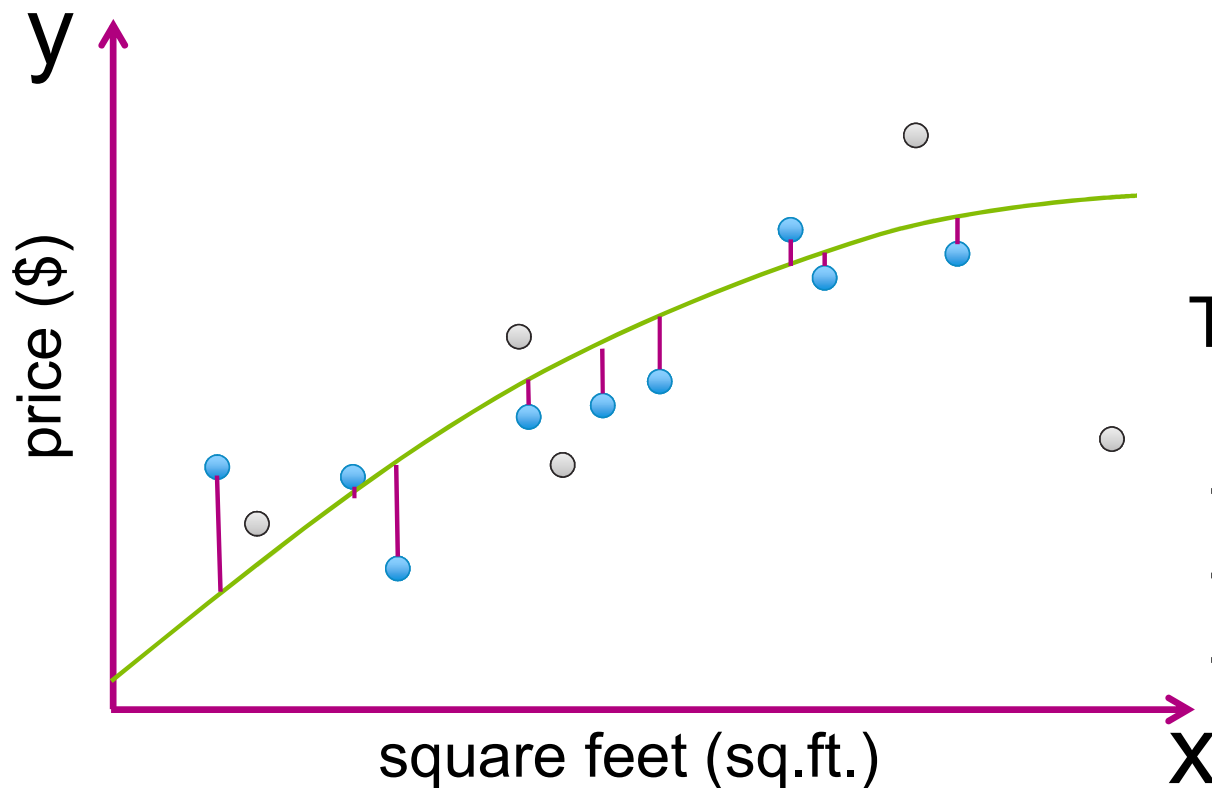

$$= \frac{1}{N} \sum_{i=1}^N L(y_i, f_{\hat{w}}(x_i))$$

fit using training data

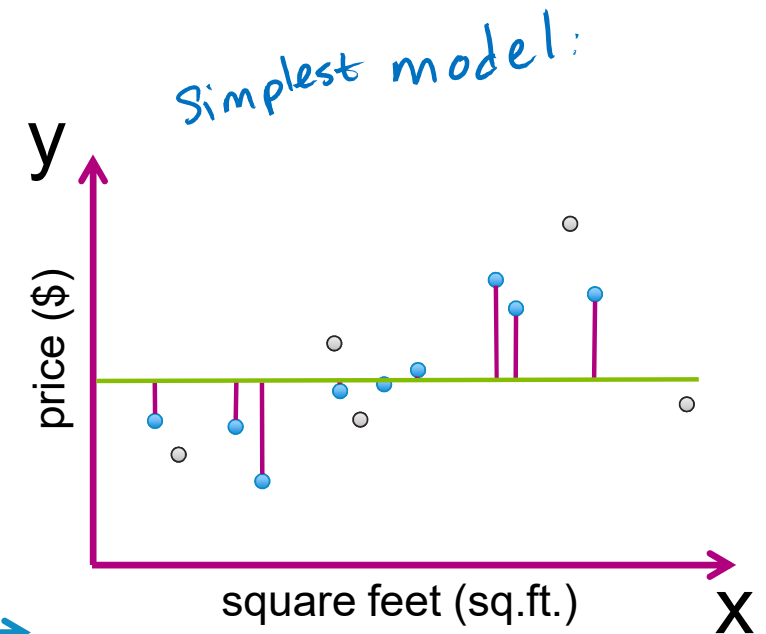

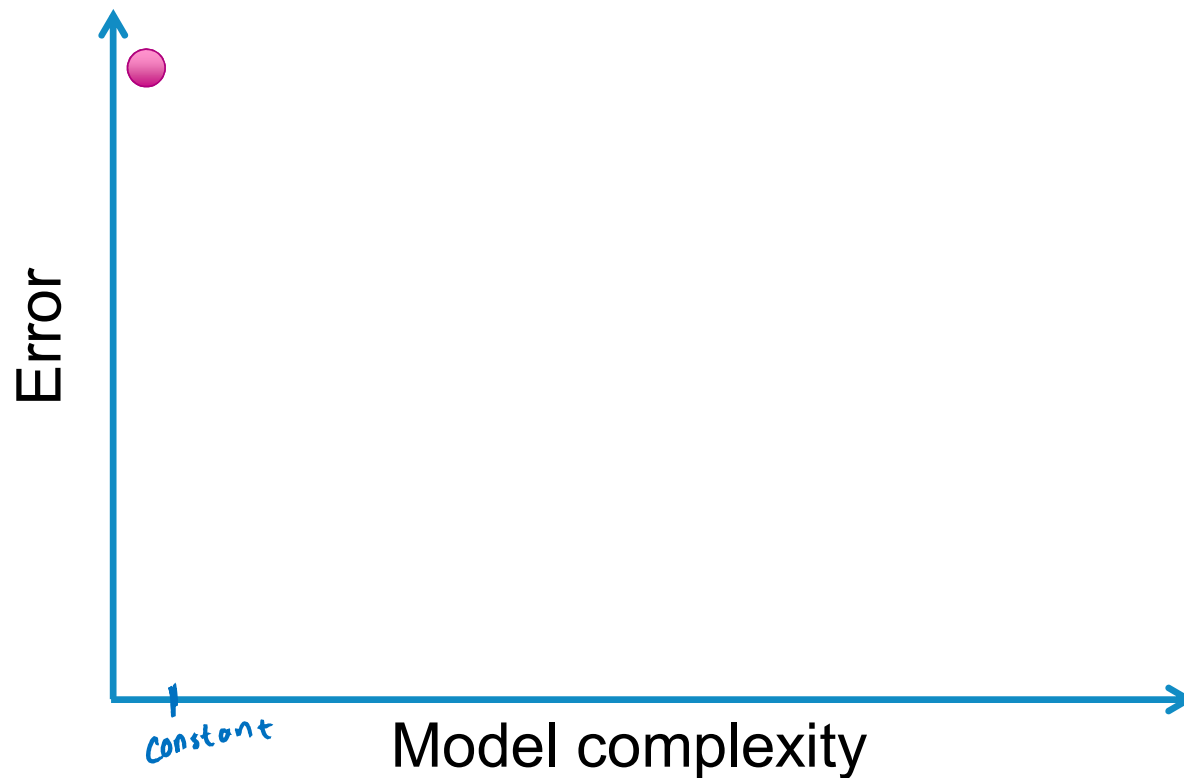

Example:

Use squared error loss  $(y - f_{\hat{w}}(x))^2$

Training error ( $\hat{w}$ ) =  $1/N * [(\$_{\text{train } 1} - f_{\hat{w}}(\text{sq.ft.}_{\text{train } 1}))^2 + (\$_{\text{train } 2} - f_{\hat{w}}(\text{sq.ft.}_{\text{train } 2}))^2 + (\$_{\text{train } 3} - f_{\hat{w}}(\text{sq.ft.}_{\text{train } 3}))^2 + \dots \text{include all training houses}]$

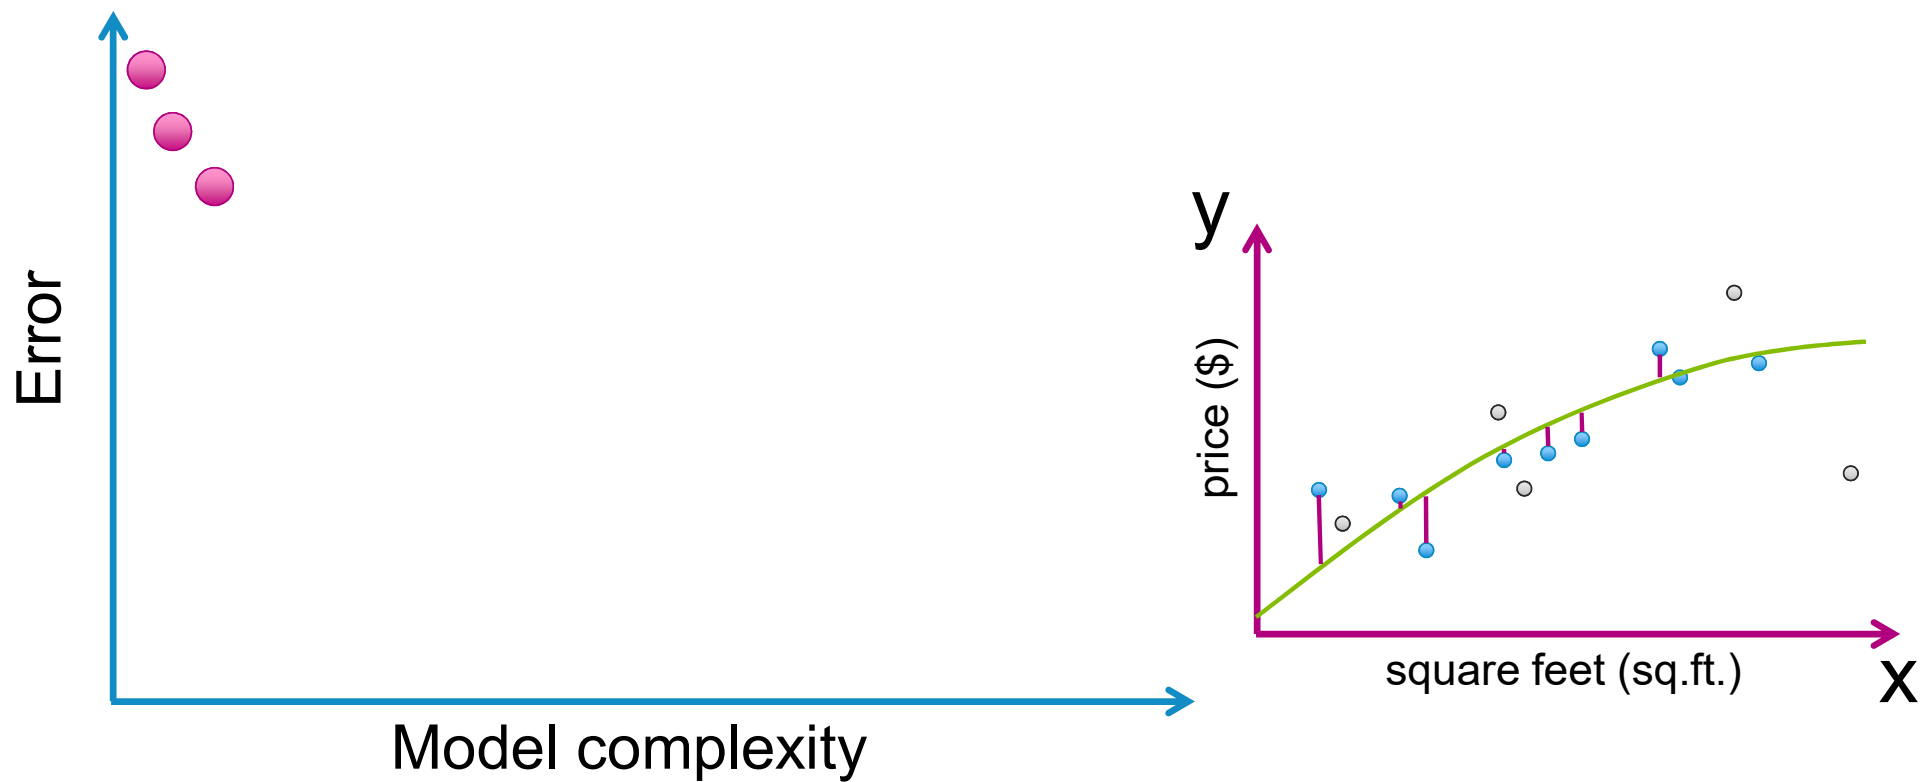

# Training error vs. model complexity

# Training error vs. model complexity

# Training error vs. model complexity

# Training error vs. model complexity

# Training error vs. model complexity

# Assessing the loss

## Part 2: Generalization (true) error

# Generalization error

Really want estimate of loss over all possible (🏠, \$) pairs

# Distribution over houses

In our neighborhood, houses of what # sq.ft. (🏠) are we likely to see?

# Distribution over sales prices

For houses with a given # sq.ft. (🏠), what house prices \$ are we likely to see?

# Generalization error definition

Really want estimate of loss over all possible (🏠, \$) pairs

Formally:

average over all possible  
(x,y) pairs weighted by  
how likely each is

$$\text{generalization error} = E_{x,y} [L(y, f_{\hat{w}}(x))]$$

$$= \int L(y, f_{\hat{w}}(x)) p(x,y) dx dy$$

fit using training data

# Generalization error vs. model complexity

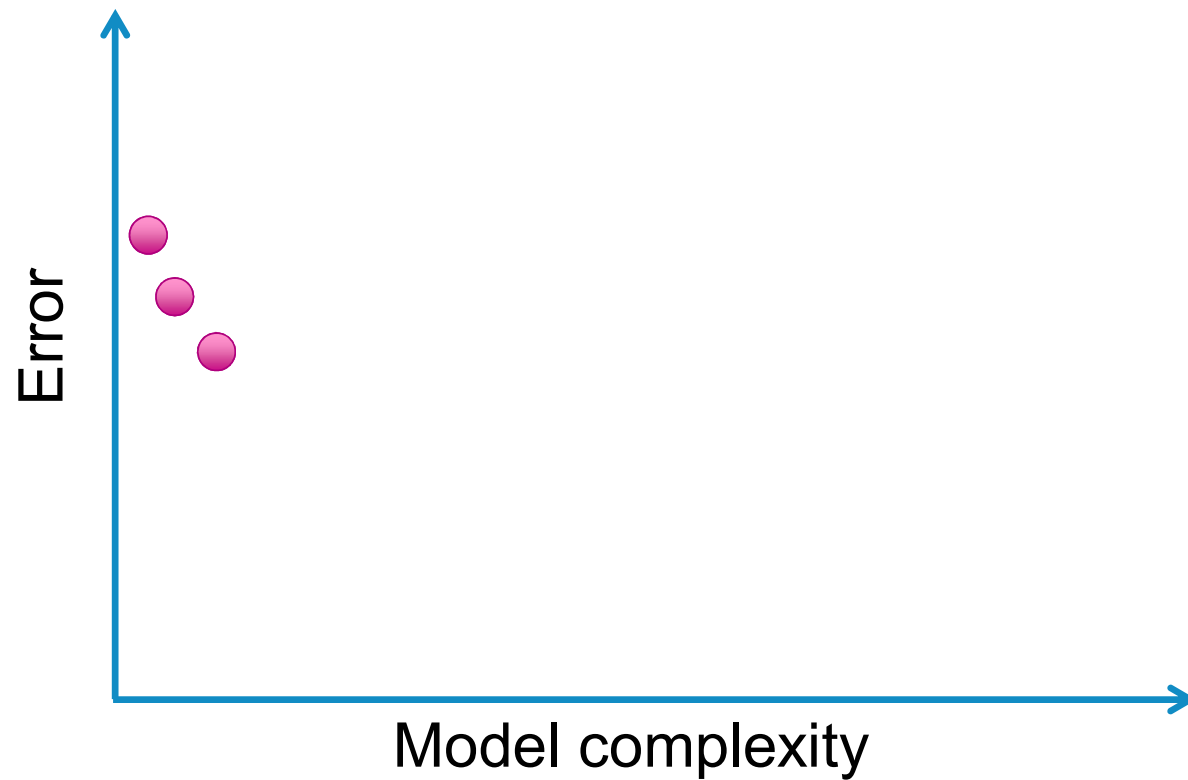

# Generalization error vs. model complexity

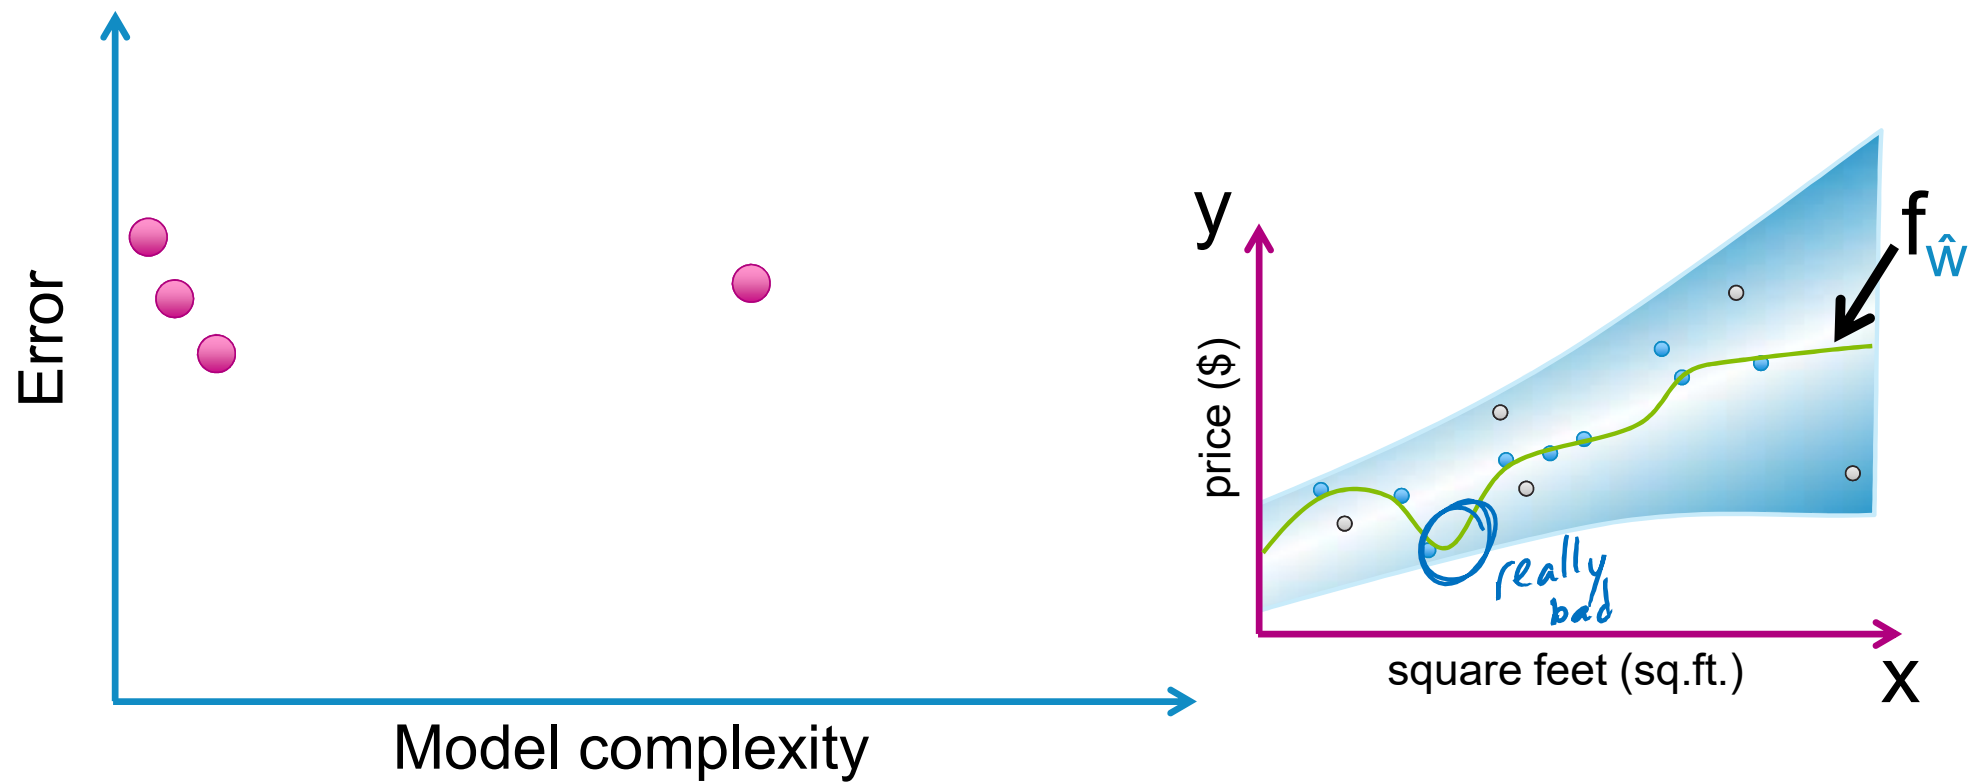

# Generalization error vs. model complexity

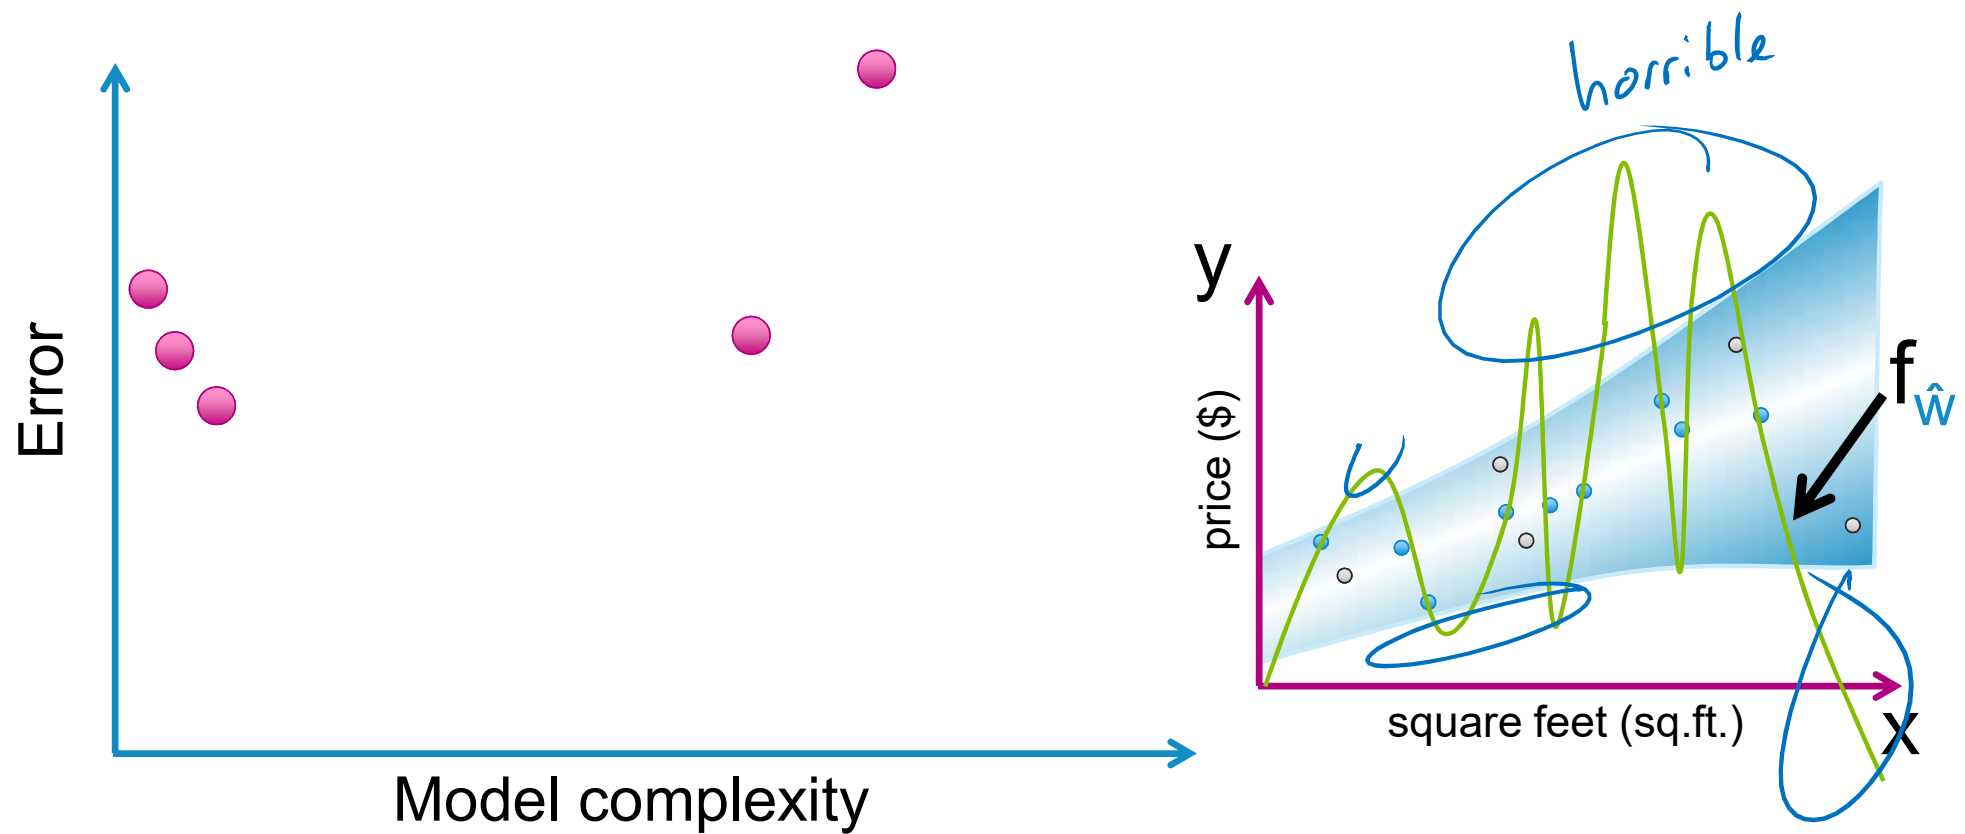

# Generalization error vs. model complexity

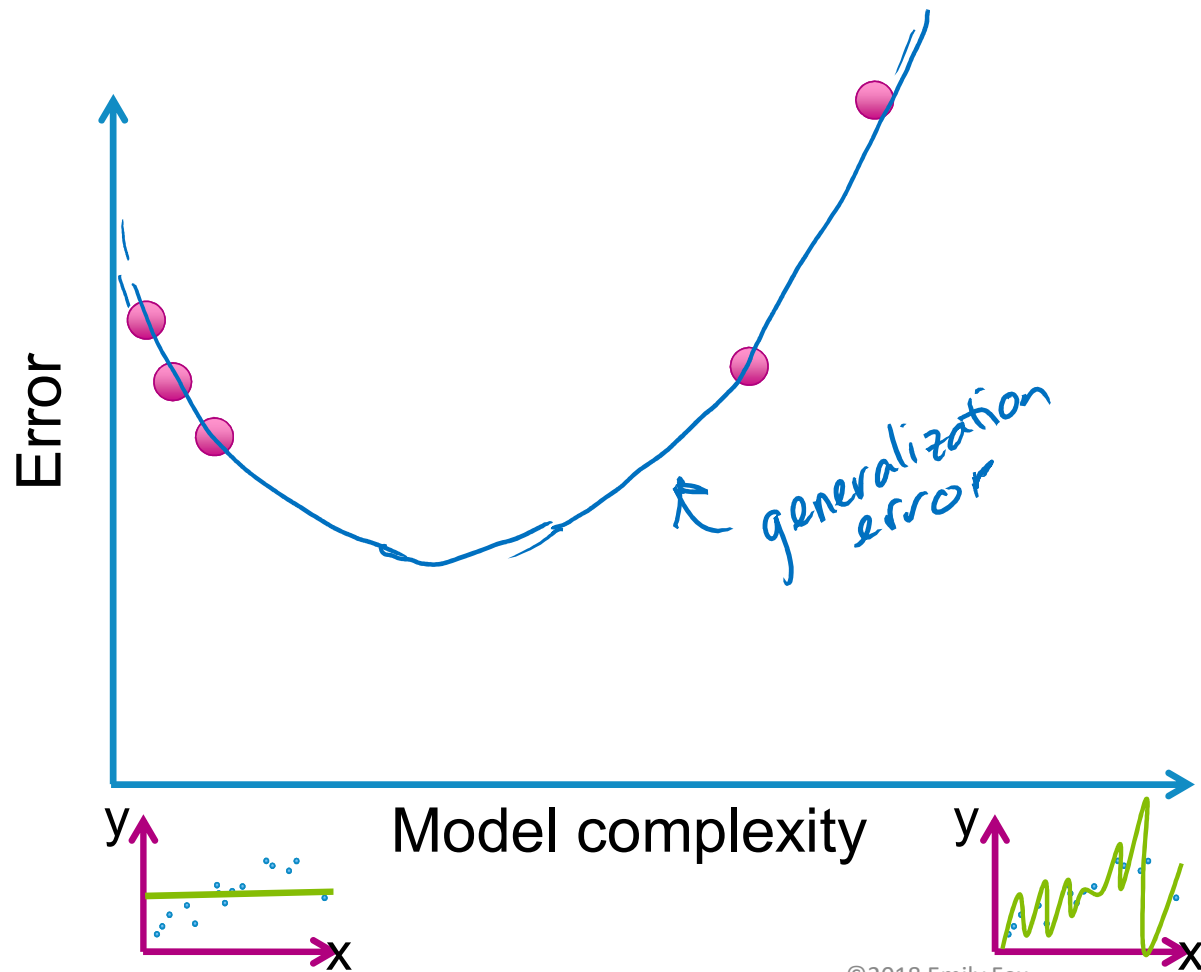

# Generalization error vs. model complexity

# Generalization error vs. model complexity

# Generalization error vs. model complexity

Can't compute!

# Assessing the loss

## Part 3: Test error

# Approximating generalization error

Wanted estimate of loss over all possible (🏠, \$) pairs

Approximate by looking at houses not in training set

# Forming a test set

Hold out some (🏠, \$) that are *not* used for fitting the model

Training set

Test set

# Forming a test set

Hold out some ( \$ ) that are *not* used for fitting the model

Proxy for “everything you might see”

Test set

# Compute test error

## Test error

= avg. loss on houses in **test set**

$$= \frac{1}{N_{test}} \sum_{i \text{ in test set}} L(y_i, f_{\hat{w}}(x_i))$$

# test points

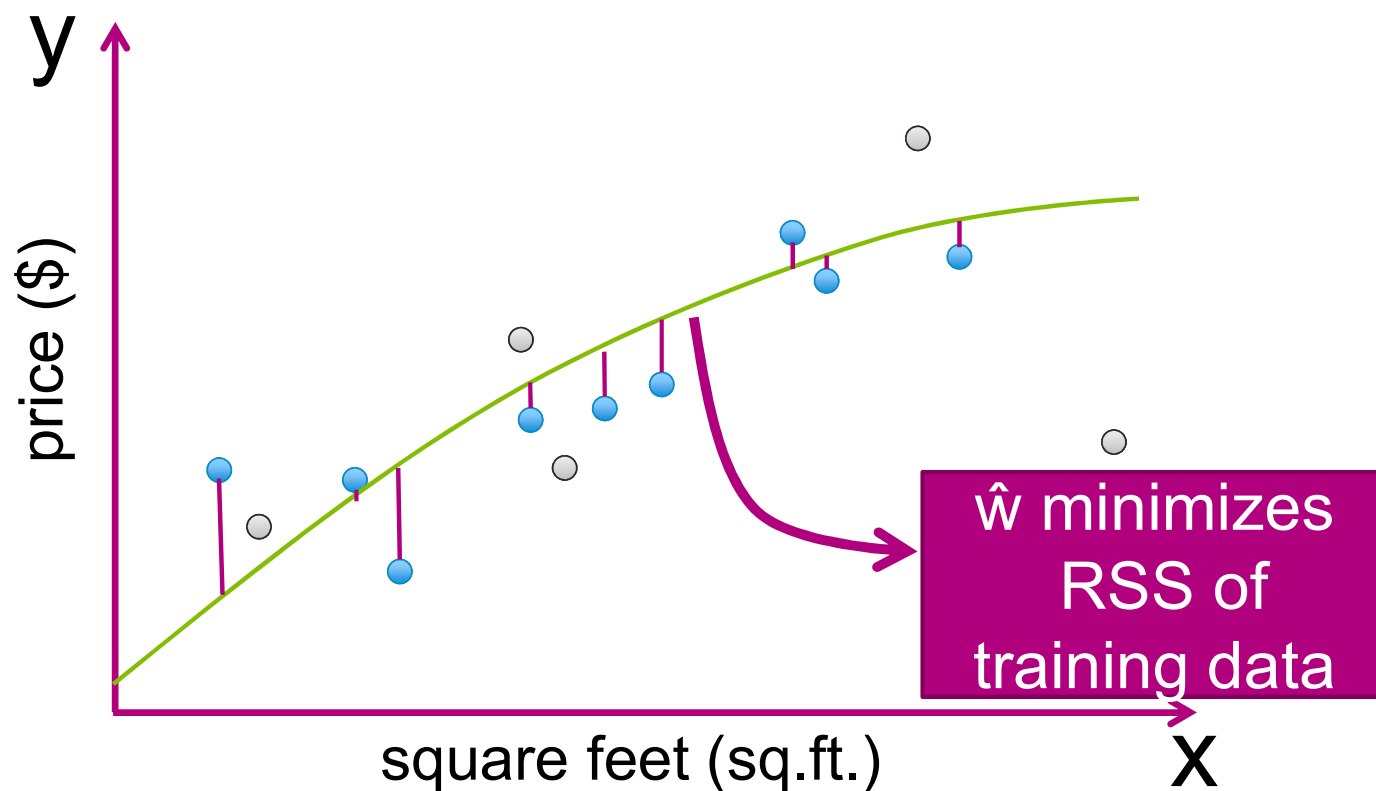

fit using **training data**

has never seen  
test data!

super important!  
Don't train on test data

Example:

As before, fit quadratic to training data

Example:

As before, use squared error loss  $(y - f_{\hat{w}}(x))^2$

$$\begin{aligned} \text{Test error } (\hat{w}) &= 1/N_{\text{test}} * \\ & [(\$_{\text{test } 1} - f_{\hat{w}}(\text{sq.ft.}_{\text{test } 1}))^2 \\ & + (\$_{\text{test } 2} - f_{\hat{w}}(\text{sq.ft.}_{\text{test } 2}))^2 \\ & + (\$_{\text{test } 3} - f_{\hat{w}}(\text{sq.ft.}_{\text{test } 3}))^2 \\ & + \dots \text{ include all} \\ & \text{test houses}] \end{aligned}$$

# Training, true, & test error vs. model complexity

test is a noisy approx  
of true error

## Overfitting if:

You learn a model w/param  $w$ ,  
but there exists a model  
w/param  $w'$  such that

- 1)  $\text{true error}(w') < \text{true error}(w)$
- 2)  $\text{train error}(w) < \text{train error}(w')$

# Training/test split

# Training/test splits

*whole dataset*

↑  
how many? vs. how many?  
↑

# Training/test splits

Too few  $\rightarrow \hat{w}$  poorly estimated

- Only 2 train points
- could be linear
  - could be quadratic
  - Who knows?

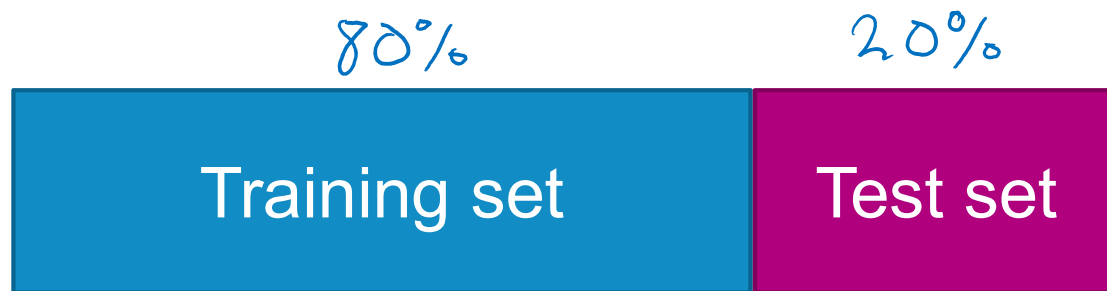

# Training/test splits

Too few  $\rightarrow$  test error bad approximation of true error

# Training/test splits

Typically, just enough test points to form a reasonable estimate of true error

If this leaves too few for training, other methods like cross validation (will see later...)

# 3 sources of error + the bias-variance tradeoff

# 3 sources of error

In forming predictions, there are 3 sources of error:

1. **Noise**

*How your model deals with*

2. **Bias**

- *Signal*

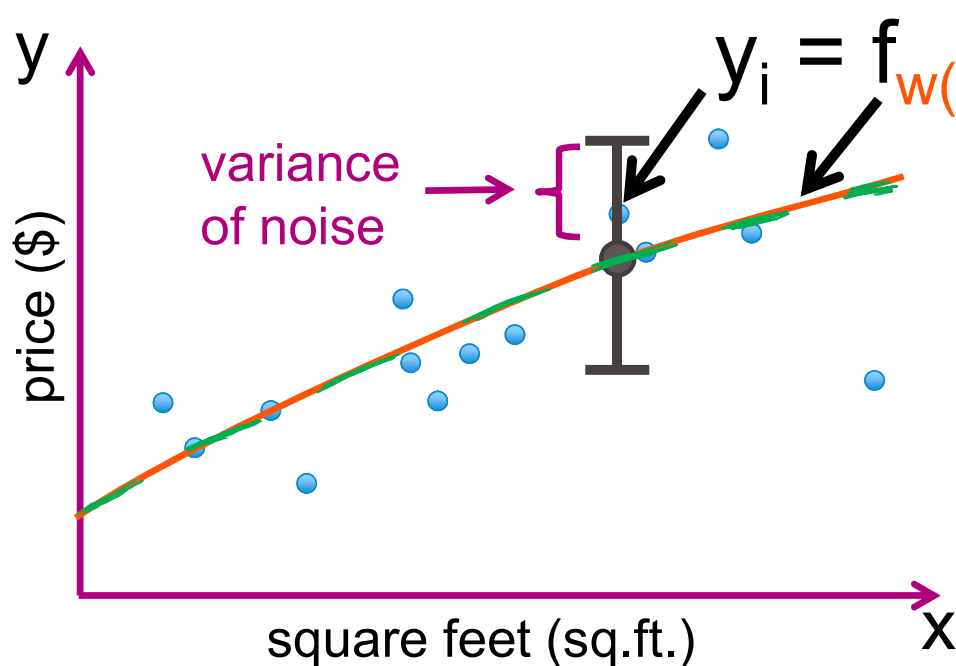

3. **Variance**

- *Noise*

# Data inherently noisy

$$E[\varepsilon_i] = 0$$

$$\text{Var}(\varepsilon_i) = \sigma^2$$

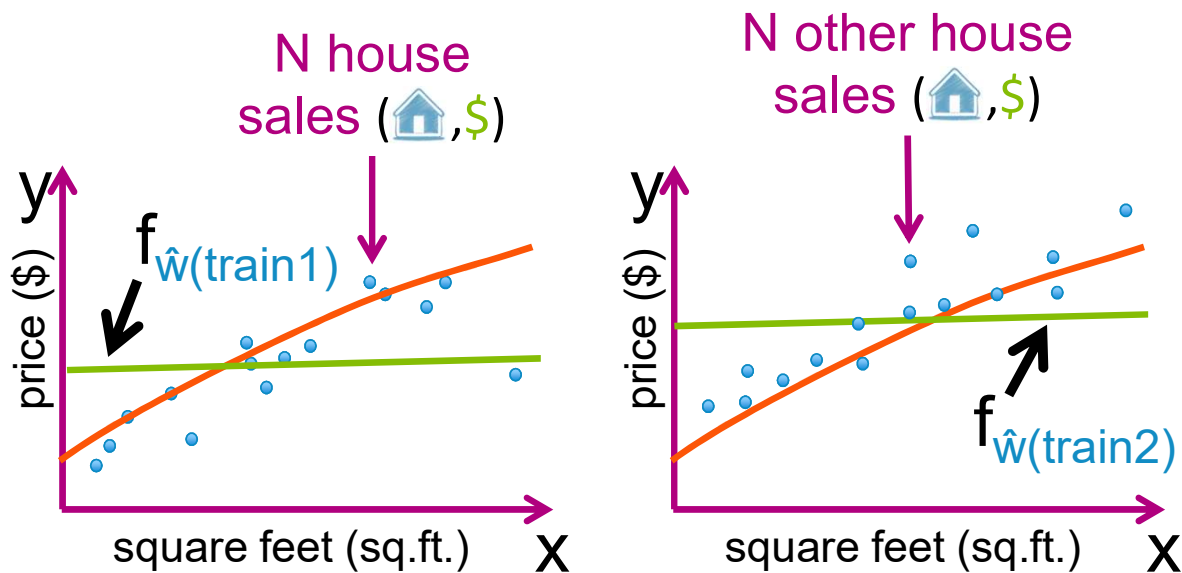

Even if  $f_{\hat{w}} = f_{w(\text{true})}$ , will have error due to  $\varepsilon_i$

**Irreducible error**

# Bias contribution

Assume we fit a constant function

# Bias contribution

Over all possible size  $N$  training sets, what do I expect my fit to be?

# Bias contribution

$\text{Bias}(x) = f_{w(\text{true})}(x) - f_{\bar{w}}(x)$  ← Is our approach flexible enough to capture  $f_{w(\text{true})}$ ?  
If not, error in predictions.

low complexity  
→  
high bias

# Variance contribution

How much do specific fits vary from the expected fit?

# Variance contribution

How much do specific fits vary from the expected fit?

# Variance contribution

How much do specific fits vary from the expected fit?

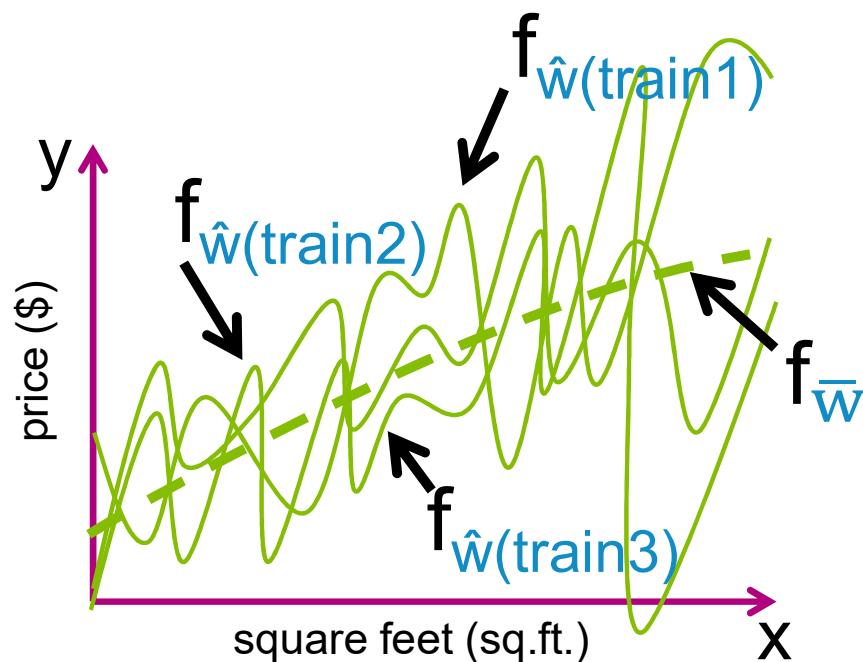

# Variance of high-complexity models

Assume we fit a high-order polynomial

# Variance of high-complexity models

Assume we fit a high-order polynomial

# Variance of high-complexity models

high complexity  
→  
high variance

# Bias of high-complexity models

high complexity  
→  
low bias

# Bias-variance tradeoff

$$\text{error} = \text{bias}^2 + \text{variance} + \text{noise}$$

Simple Models

Bias: High

Variance: Low

Complex Models

Bias: Low

Variance High

# Error vs. amount of data for fixed model complexity

# Summary of assessing performance

# What you can do now...

- Describe what a loss function is and give examples
- Contrast training and test error
- Compute training and test error given a loss function
- Discuss issue of assessing performance on training set
- Describe tradeoffs in forming training/test splits
- List and interpret the 3 sources of avg. prediction error
  - Irreducible error, bias, and variance
