Pre-Lecture Video 1

Classification

Logistics

Homework 2 out, due this Friday

A bit more challenging than the first one so you should try to start early

COVID concerns: I and some of my staff members are still dealing with COVID situations, so we'd appreciate your patience as things can be slow.

Sorry for not releasing the re-recordings over the weekends. Will finish them today. Hopefully will help you for hw2. In the mean time you can watch Hunter's.

Roadmap So Far

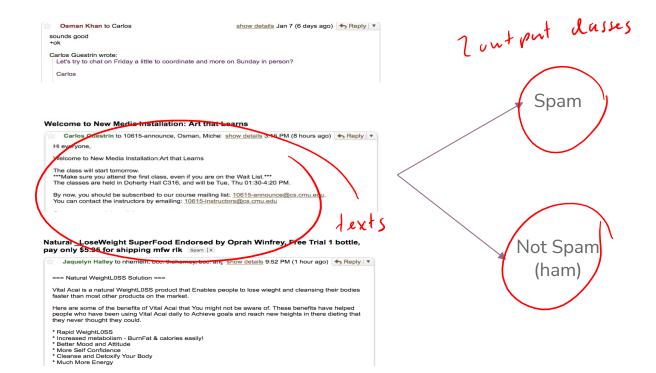

- Housing Prices Regression (xy) continuous value

- Regression Model
- **Assessing Performance**
- Ridge Regression
- **LASSO**

- J Regularization -Overithing
- Sentiment Analysis Classification
 - Classification Overview
 - Logistic Regression

Spam Filtering

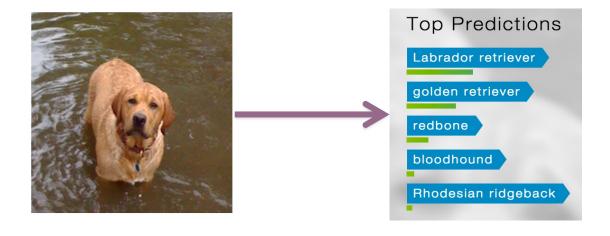

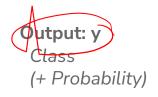

Text of email Sender Subject Output: y
Spam
Ham

. . .

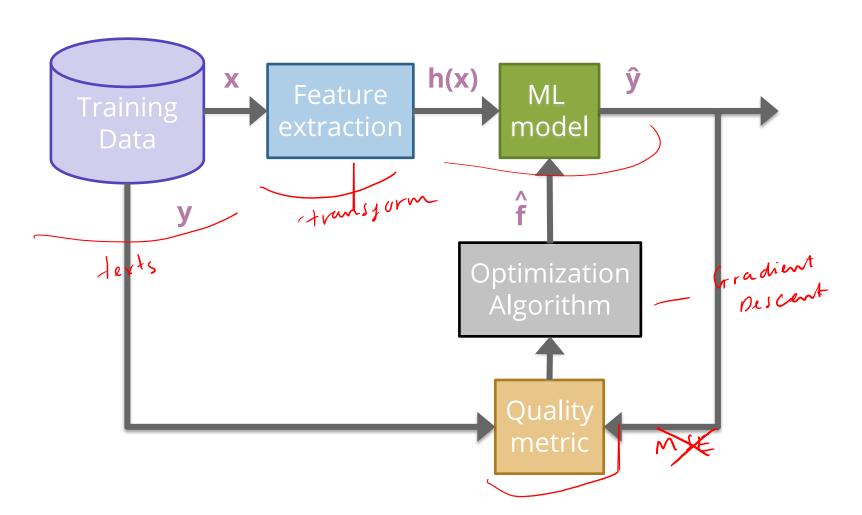

Object Detection

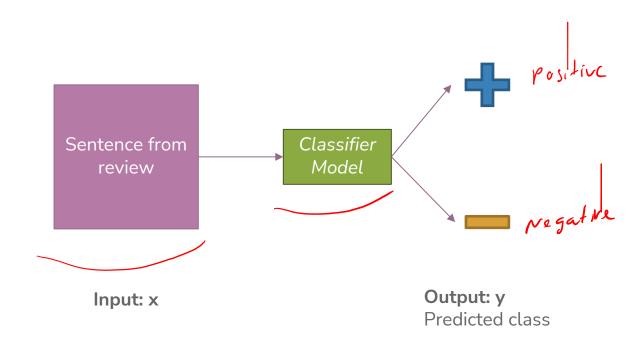

Sentiment Classifier

In our example, we want to classify a restaurant review as positive or negative.

Implementation 1: Simple Threshold Classifier

Idea: Use a list of good words and bad words, classifier by most frequent type of word

Positive Words: great, awesome, good, amazing, ...

Negative Words: bad, terrible, disgusting, sucks, ...

Simple Threshold Classifier

Input x: Sentence from review

Count the number of positive and negative words, in x

If num_positive > num_negative:

$$-\hat{y} = +1$$

Else:

$$- \hat{y} = -1$$

Example: "Sushi was great, the food was awesome, but the service was terrible"

Limitations of **Implementation**

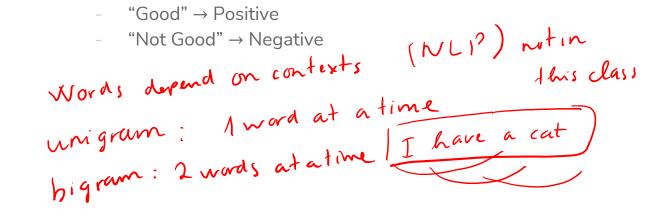

How do we get list of positive/negative words?

Words have different degrees of sentiment.

- Great > Good
- How can we weigh them differently?

Single words are not enough sometimes...

- "Good" → Positive

Implementation 2: Linear Classifier

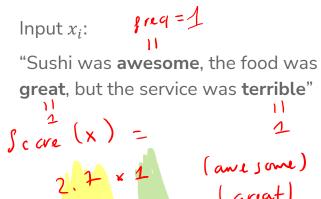

Idea: Use labelled training data to learn a weight for each word. Use weights to score a sentence.

Word	Weight	
good	1.0	Live
great	1.5	positive
awesome	2.7	
bad	1.0	
terrible	-2.1	negative
awful	-3.3	
restaurant, the, we, where,	. (0.0)	nentral

Score a Sentence

Word	Weight
good	1.0
great	1.5
awesome	2.7
bad	-1.0
terrible	-2.1
awful	-3.3
restaurant, the, we, where,	0.0
•••	•••

= 2.1 =) positive

Linear classifier, because output is linear weighted sum of inputs.

Will learn how to learn weights soon!

Think &

1 min

What is the score of this sentence?

Word	Weight
good	1.0
great	(1.5)
awesome	2.7
bad	-1.0
terrible	-2.1
awful	-3.3
restaurant, the, we, where,	0.0
•••	•••

Input x_i :

"Sushi was **awful**, but the food was **great**, and the service was **great** as well".

$$S_{core}(x)$$
= $(-3.3) \times 1$
+ 1.5×2
= $-0.3 \implies predicted:$
regative

Implementation 2: Linear Classifier

Idea: Use labelled training data to learn a weight for each word. Use weights to score a sentence.

See last slide for example weights and scoring.

Linear Classifier

Input *x*: Sentence from review

Compute Score(x)

If
$$Score(x) > 0$$
:
$$\hat{y} = +1$$

Else:

$$-\hat{y} = -1$$

Linear Classifier Notation

Model:
$$\hat{y}^{(i)} = sign\left(Score(x^{(i)})\right)$$

$$Score(x_i) = \underline{w_0}h_0(x^{(i)}) + \underline{w_1}h_1(x^{(i)}) + \dots + \underline{w_D}h_D(x^{(i)})$$

$$= \sum_{j=0}^{D} w_j h_j(x^{(i)}) \qquad \text{for a res}$$

$$= w^T h(x^{(i)})$$

We will also use the notation

$$\hat{s}^{(i)} = Score(x^{(i)}) = w^{T}h(x^{(i)})$$

$$\hat{y}^{(i)} = sign(\hat{s}^{(i)})$$

Decision Boundary

Consider if only two words had non-zero coefficients

Word	Coefficient	Weight	$\hat{s} = 1 \cdot \#awesome - 1.5 \cdot \#awful$
	w_0	0.0	
awesome	W_1	1.0	
awful	W_2	-1.5	negative
#awful		F	
: (1.5. *AUNFUL TO	
4		5. Hawl	
$^{\circ}$	O O one		€ ← positive
7	· * due some	0 0	
\leftarrow			
0			#awesome

Limitations of Implementation 2

Words are not single on their own, but depend on surrounding contexts:

"Not not good" -> positive

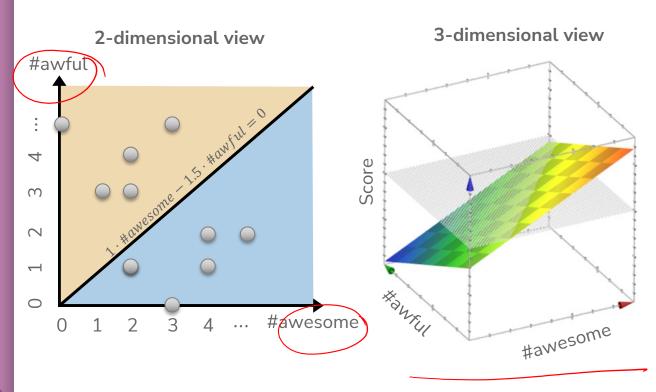

A bit sad -> negative (but not low negative score)

Linear classifier can't learn complex models well

Decision Boundary

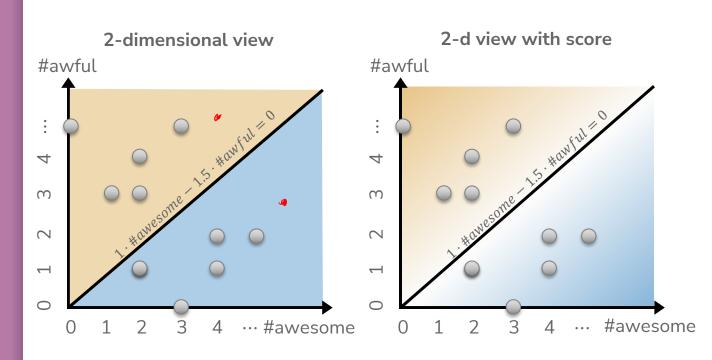

$Score(x) = 1 \cdot \#awesome - 1.5 \cdot \#awful$

Generally, with classification we don't us a plot like the 3d view since it's hard to visualize, instead use 2d plot with decision boundary

Decision Boundary

$Score(x) = 1 \cdot \#awesome - 1.5 \cdot \#awful$

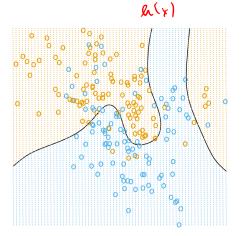

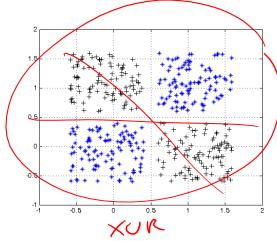

Class Session

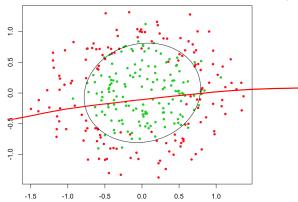

Complex Decision Boundaries?

What if we want to use a more complex decision boundary?

Need more complex model/features!

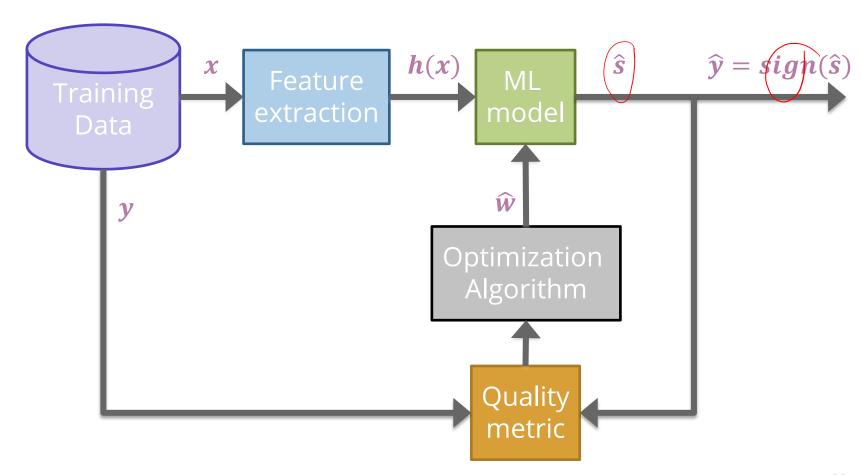

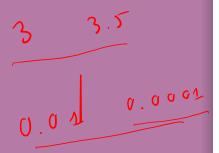

Evaluating Classifiers

Classification Error

Ratio of examples where there was a mistaken prediction

What's a mistake?

If the true label was positive (y = +1),

but we predicted negative ($\hat{y} = -1$)

If the true label was negative (y = -1), but we predicted positive ($\hat{y} = +1$)

Classification Error

lassification Error

$$\frac{\text{H mistukes}}{\text{H oxamples}} = \frac{1}{n} \sum_{i} \underbrace{1} \left(y^{(i)} \pm \hat{y}^{(i)} \right)$$

Classification Accuracy

What's a good accuracy?

For binary classification:

Should at least beat random guessing...

Accuracy should be at least 0.5

example

For multi-class classification (k. dasses):

Should still beat random guessing

Accuracy should be at least $\frac{1}{k}$

- 3-class: 0.33

4-class: 0.25

- ...

Besides that, higher accuracy means better, right?

Detecting Spam

Imagine I made a "Dummy Classifier" for detecting spam

The classifier ignores the input, and always predicts spam.

This actually results in 90% accuracy! Why?

- Most emails are spam...

This is called the majority class classifier.

A classifier as simple as the majority class classifier can have a high accuracy if there is a **class imbalance**.

A class imbalance is when one class appears much more frequently than another in the dataset

This might suggest that accuracy isn't enough to tell us if a model is a good model.

Assessing Accuracy

Always digging in and ask critical questions of your accuracy.

Is there a class imbalance?

How does it compare to a baseline approach?

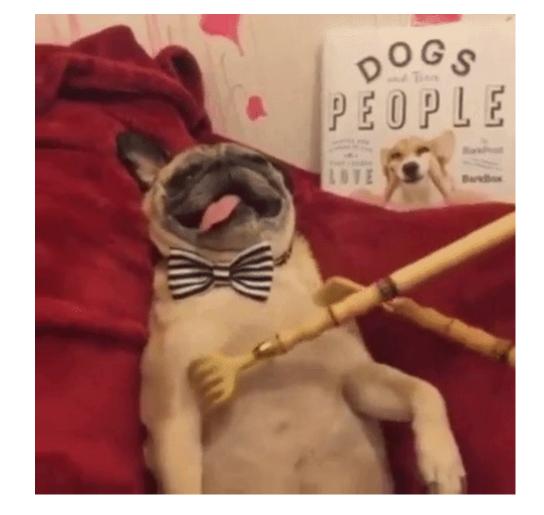

- Random guessing
- Majority class
- ..

Most important: What does my application need?

- What's good enough for user experience?
- What is the impact of a mistake we make?

📆 Brain Break

Confusion Matrix

For binary classification, there are only two types of mistakes

$$\hat{y} = +1$$
, $y = -1$

$$\hat{y} = -1, \ y = +1$$

Generally we make a confusion matrix to understand mistakes.

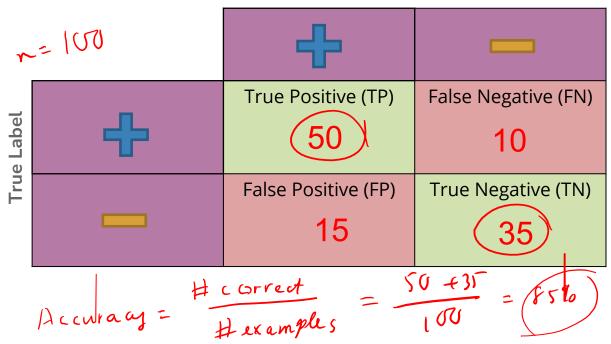

Predicted Label

		4	
e Label	4	True Positive (TP)	False Negative (FN)
True		False Positive (FP)	True Negative (TN)

Confusion Matrix Example

Predicted Label

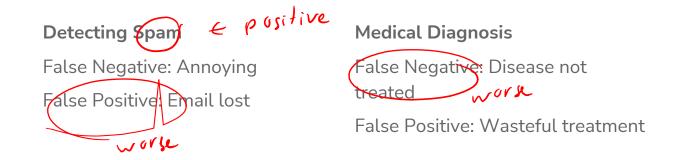

Which is Worse?

What's worse, a false negative or a false positive?

It entirely depends on your application!

In almost every case, how treat errors depends on your context.

Think &

2 mins

In your group, discuss an example of the social implications using machine learning classifiers in making decisions.

Errors and Fairness

We mentioned on the first day how ML is being used in many contexts that impact crucial aspects of our lives.

Models making errors is a given, what we do about that is a choice:

Are the errors consequential enough that we shouldn't use a model in the first place?

Do different demographic groups experience errors at different rates?

If so, we would hopefully want to avoid that model!

Will talk more about how to define whether or a not a model is fair / discriminatory in a later lecture! Will use these notions of error as a starting point!

Binary Classification Measures

Notation

$$C_{TP} = \text{\#TP}, \ C_{FP} = \text{\#FP}, \ C_{TN} = \text{\#TN}, \ C_{FN} = \text{\#FN}$$
 $N = C_{TP} + C_{FP} + C_{TN} + C_{FN}$
 $N_P = C_{TP} + C_{FN}, \ N_N = C_{FP} + C_{TN}$

Error Rate

$$\frac{C_{FP} + C_{FN}}{N}$$

Accuracy Rate

$$\frac{C_{TP} + C_{TN}}{N}$$

False Positive rate (FPR)

$$\frac{C_{FP}}{N_N}$$

False Negative Rate (FNR)

$$\frac{C_{FN}}{N_P}$$

True Positive Rate or

Recall

$$\frac{C_{TP}}{N_P}$$

Precision

$$\frac{C_{TP}}{C_{TP} + C_{FP}}$$

F1-Score

$$2 \frac{Precision \cdot Recall}{Precision + Recall}$$

See morel

Multiclass Confusion Matrix

Consider predicting (Healthy, Cold, Flu)

		Predicted Label		
		Healthy	Cold	Flu
	Healthy	60	8	2
True Label	Cold	4	12	4
	Flu	0	2	8

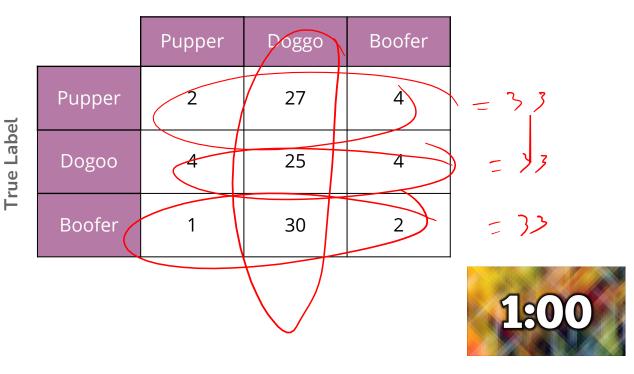

Think &

1 min

pollev.com/cs416

Suppose we trained a classifier and computed its confusion matrix on the training dataset. Is there a class imbalance in the dataset and if so, which class has the highest representation?

Predicted Label

Think &

2 min

pollev.com/cs416

Suppose we trained a classifier and computed its confusion matrix on the training dataset. Is there a class imbalance in the dataset and if so, which class has the highest representation?

Predicted Label

	Pupper	Doggo	Boofer
Pupper	2	27	4
Doggo	4	25	4
Boofer	1	30	2

Learning Theory

How much data?

The more the merrier

But data quality is also an extremely important factor

Theoretical techniques can bound how much data is needed

Typically too loose for practical applications

But does provide some theoretical guarantee

In practice

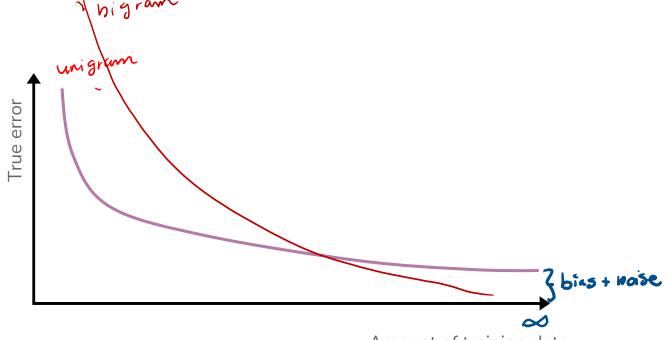

More complex models need more data

Learning Curve

How does the true error of a model relate to the amount of training data we give it?

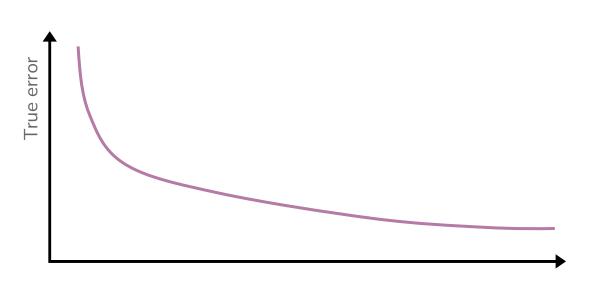

Hint: We've seen this picture before

Learning Curve

What if we use a more complex model?

📆 Brain Break

Threshold Model

Change Threshold

What if I never want to make a false positive prediction?

What if I never want to make a false negative prediction?

One way to control for our application is to change the scoring threshold. (Could also change intercept!)

If
$$Score(x) > \alpha$$
:

Predict $\hat{y} = +1$

Else:

- Predict
$$\hat{y} = -1$$

Next Time

We will talk about learning classifiers that model the probability of seeing a particular class at a given input.

Normally assume some structure on the probability (e.g. linear) $P(y|x,w)\approx w^Tx$

Use machine learning algorithm to learn approximate \widehat{w} such that $\widehat{P}(y|x) = P(y|x,\widehat{w})$

And P(y|x) and $\hat{P}(y|x)$ are close.

Recap

Theme: Describe high level idea and metrics for classification
