Clustering Reca

Clustering

WORLD NEWS

Define Clusters

In their simplest form, a **cluster** is defined by

- The location of its center (centroid)
- Shape and size of its **spread**

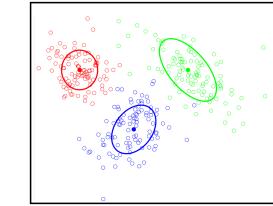

Clustering is the process of finding these clusters and **assigning** each example to a particular cluster.

 x_i gets assigned $z_i \in [1, 2, ..., k]$

Usually based on closest centroid

Will define some kind of score for a clustering that determines how good the assignments are

Based on distance of assigned examples to each cluster

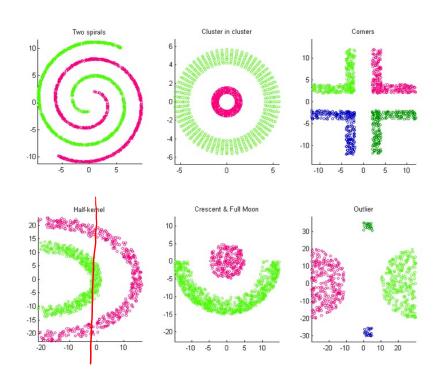

Not Always Easy

There are many clusters that are harder to learn with this setup

Distance does not determine clusters

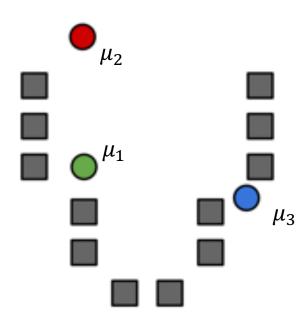

Step 0

Start by choosing the initial cluster centroids

A common default choice is to choose centroids at random Will see later that there are smarter ways of initializing

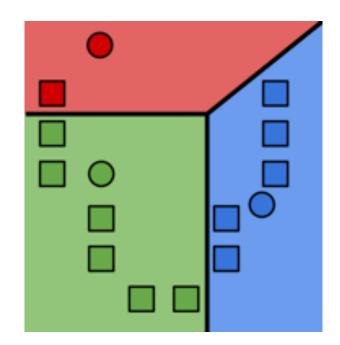

Step 1

Assign each example to its closest cluster centroid

$$z_i \leftarrow \underset{j \in [k]}{\operatorname{argmin}} \left| \left| \mu_j - x_i \right| \right|^2$$

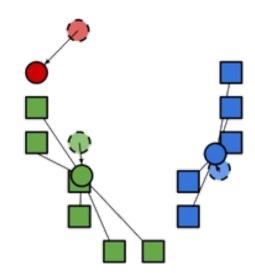

Step 2

Update the centroids to be the mean of all the points assigned to that cluster.

$$\mu_j \leftarrow \frac{1}{n_j} \sum_{i: z_i = j} x_i$$

Computes center of mass for cluster!

Smart Initializing w/ k-means++

Making sure the initialized centroids are "good" is critical to finding quality local optima. Our purely random approach was wasteful since it's very possible that initial centroids start close together.

Idea: Try to select a set of points farther away from each other.

k-means++ does a slightly smarter random initialization

- 1. Choose first cluster μ_1 from the data uniformly at random
- 2. For the current set of centroids (starting with just μ_1), compute the distance between each datapoint and its closest centroid
- 3. Choose a new centroid from the remaining data points with probability of x_i being chosen proportional to $d(x_i)^2$
- Repeat 2 and 3 until we have selected k centroids

Problems with k-means

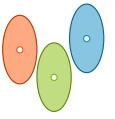

In real life, cluster assignments are not always clear cut

E.g. The moon landing: Science? World News? Conspiracy?

Because we minimize Euclidean distance, k-means assumes all the clusters are spherical

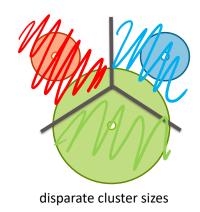

We can change this with weighted Euclidean distance
Still assumes every cluster is the same shape/orientation

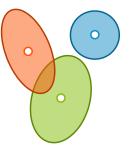

Failure Modes of k-means

If we don't meet the assumption of spherical clusters, we will get unexpected results

different shaped/oriented clusters

Mixture Models

A much more flexible approach is modeling with a **mixture model**

Model each cluster as a different probability distribution and learn their parameters

E.g. Mixture of Gaussians

Allows for different cluster shapes and sizes

Typically learned using Expectation Maximization (EM) algorithm

Allows **soft assignments** to clusters

54% chance document is about world news, 45% science, 1% conspiracy theory, 0% other

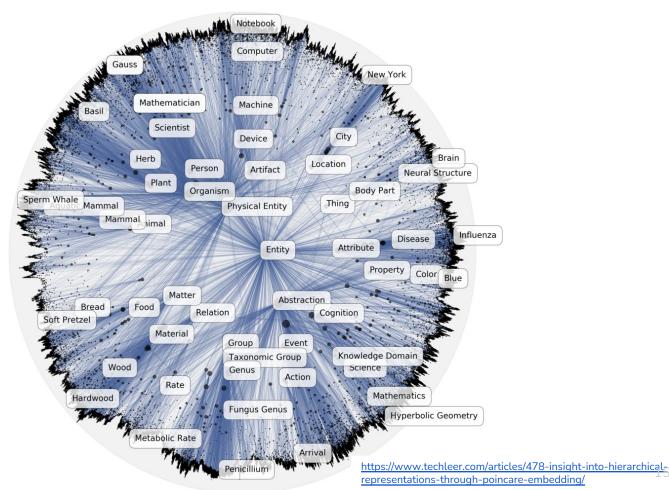

Pre-Class Video 2

Divisive Clustering

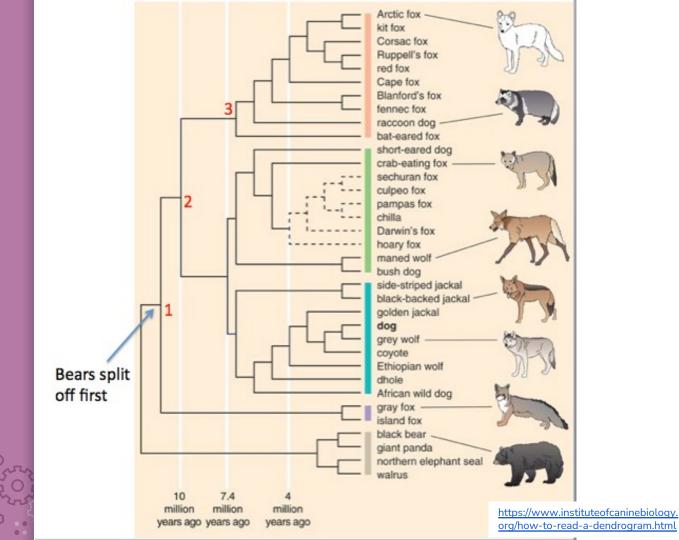

Hierarchical Clustering

Nouns

Lots of data is hierarchical by nature

Species

Motivation

If we try to learn clusters in hierarchies, we can

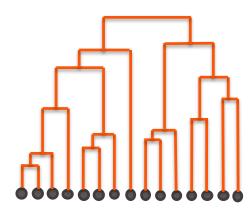

Avoid choosing the # of clusters beforehand

Use **dendrograms** to help visualize different granularities of clusters

Allow us to use any distance metric

- K-means requires Euclidean distance

Can often find more complex shapes than k-means

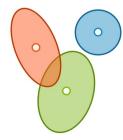

Finding Shapes

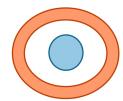

k-means

Mixture Models

Hierarchical Clustering

Types of Algorithms

Divisive, a.k.a. top-down

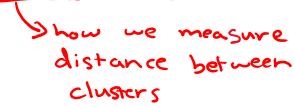

Start with all the data in one big cluster and then recursively split the data into smaller clusters

- Example: **recursive k-means**

Agglomerative, a.k.a. bottom-up:

Start with each data point in its own cluster. Merge clusters until all points are in one big cluster.

- Example: single linkage clustering

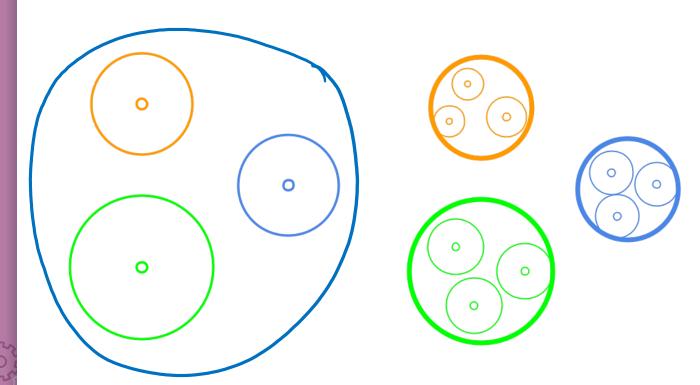

Divisive Clustering

k=3

Start with all the data in one cluster, and then repeatedly run kmeans to divide the data into smaller clusters. Repeatedly run kmeans on each cluster to make sub-clusters.

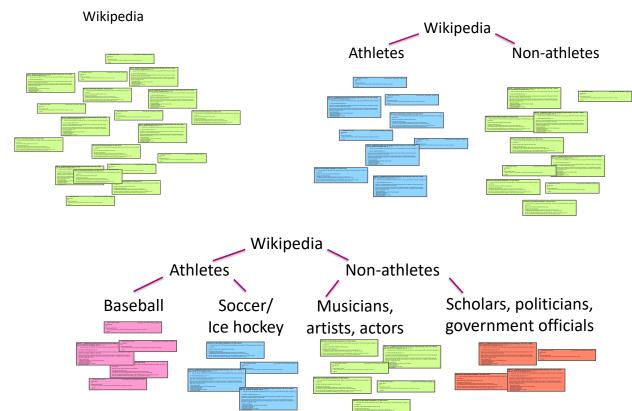

Example

K=2

Bisecting K-means

Using Wikipedia

Choices to Make

For divisive clustering, you need to make the following choices:

- Which algorithm to use (e.g., k-means)
- How many clusters per split

When to split vs when to stop

- Max cluster size
 Number of points in cluster falls below threshold
- Max cluster radius
 distance to furthest point falls below threshold
- Specified # of clusters
 split until pre-specified # of clusters is reached

Bisecting K-Means

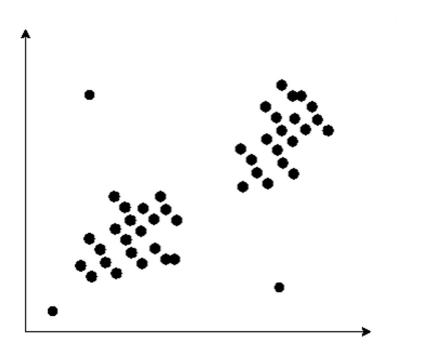

1 min

- How would you use k-means clustering to detect outliers?
- How would you use divisive clustering to detect outliers?

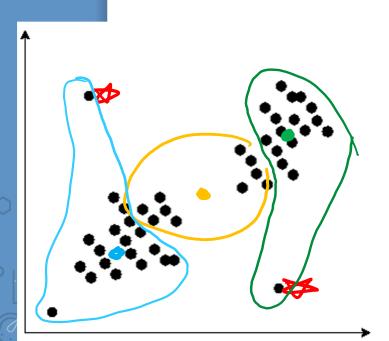

2 min

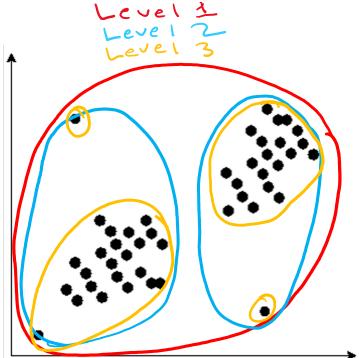

You want to detect outliers in a dataset (shown below).

 How would you use k-means clustering to detect outliers?

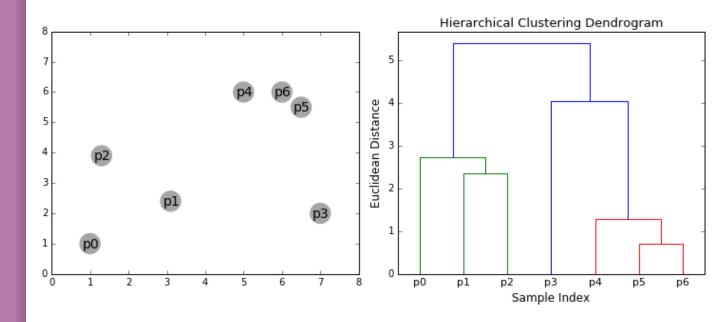

- How would you use divisive clustering to detect

outliers?

Merge closest pair of clusters

Algorithm at a glance

- 1. Initialize each point in its own cluster
- 2. Define a distance metric between clusters Hyper poramecy

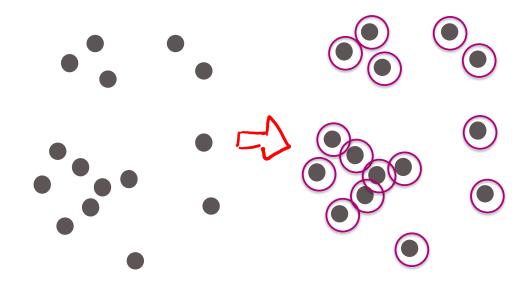

While there is more than one cluster

3. Merge the two closest clusters (and add it to dendrogram)

Step 1

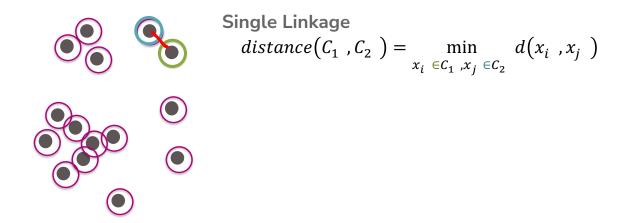

1. Initialize each point to be its own cluster

Step 2

2. Define a distance metric between clusters

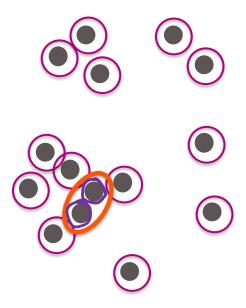

This formula means we are defining the distance between two clusters as the smallest distance between any pair of points between the clusters.

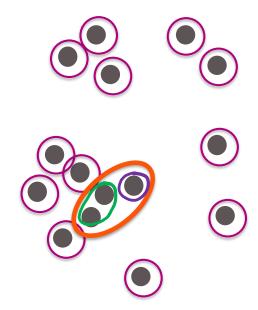

Step 3

Merge closest pair of clusters

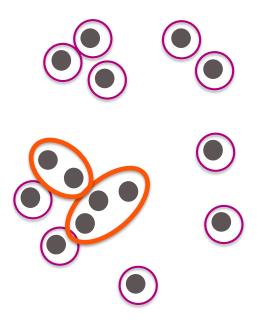

Notice that the height of the dendrogram is growing as we group points farther from each other

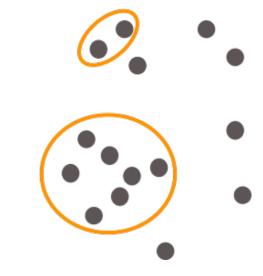

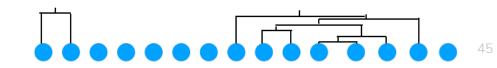

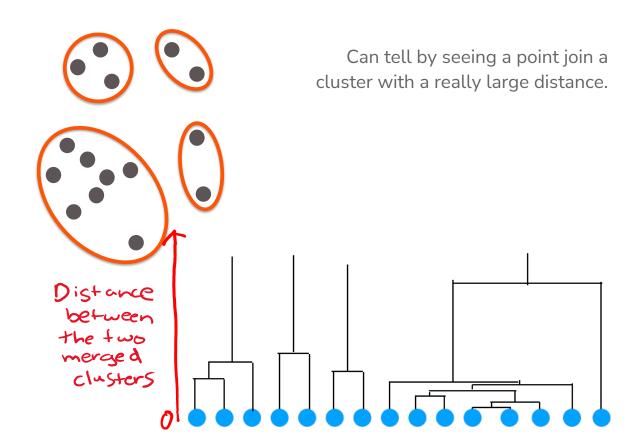

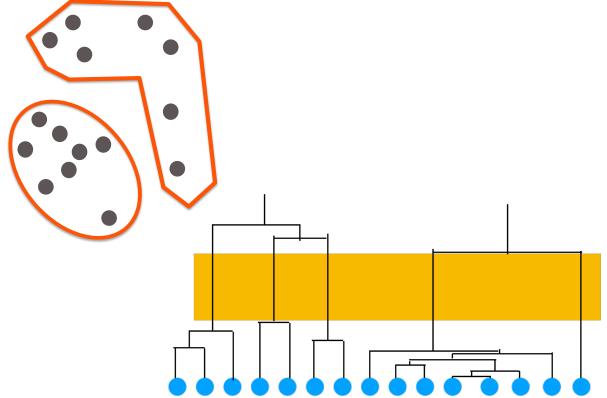

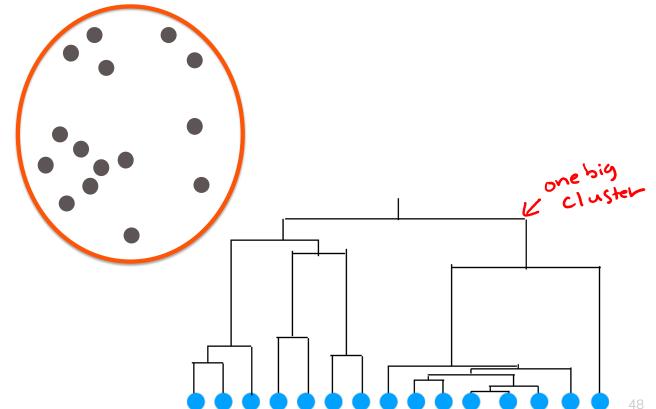

Looking at the dendrogram, we can see there is a bit of an outlier!

The tall links in the dendrogram show us we are merging clusters that are far away from each other

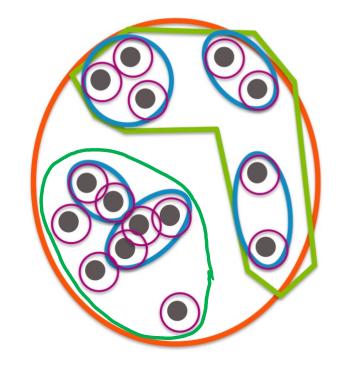

Final result after merging all clusters

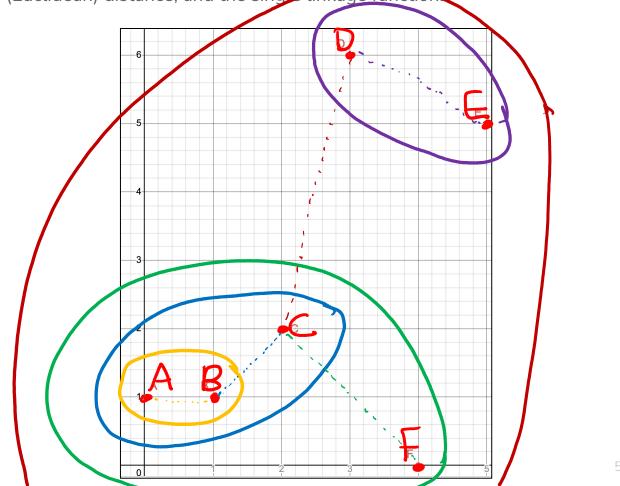

Final Result

In what order will the following points get merged into clusters? Use L2 (Euclidean) distance, and the single linkage function.

3:12

📆 Brain Break

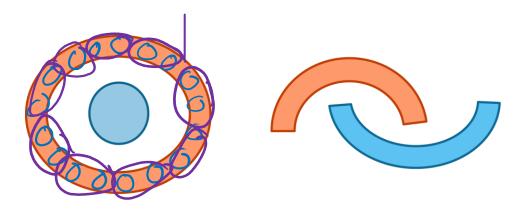

With agglomerative clustering, we are now very able to learn weirder clusterings like

Single Linkage's min dist (x; xj) x; EC, x; ECz

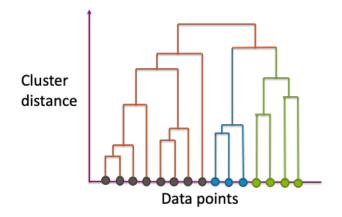

Single Linkage con merge long chains

Dendrogram

x-axis shows the datapoints (arranged in a very particular order) y-axis shows distance between merged clusters

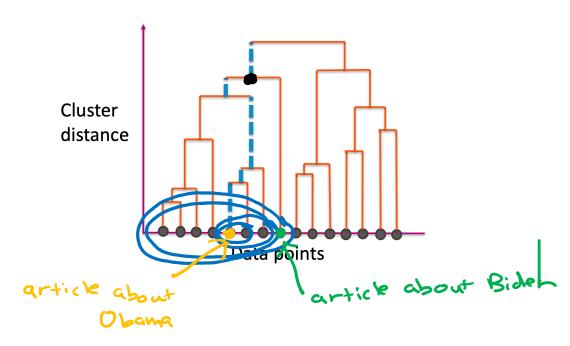

Dendrogram

The path shows you all clusters that a single point belongs and the order in which its clusters merged

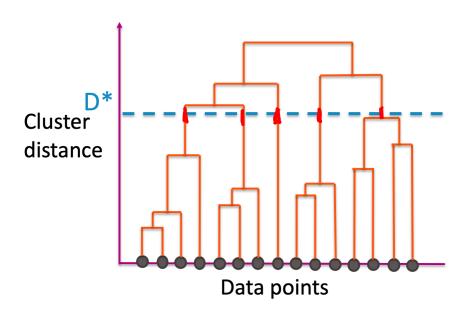

Cut Dendrogram

Choose a distance D^* to "cut" the dendrogram

Use the largest clusters with distance $< D^*$

Usually ignore the idea of the nested clusters after cutting

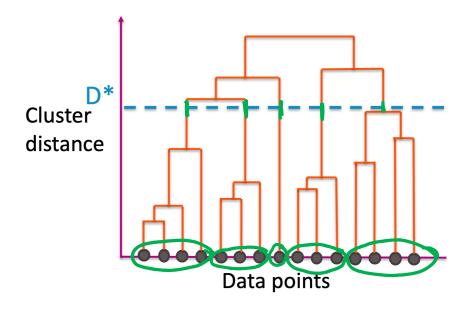

1 min

sli.do #cs416

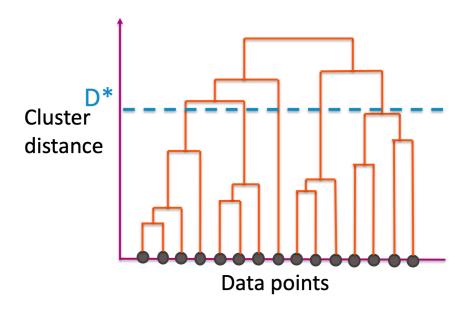

How many clusters would we have if we use this threshold?

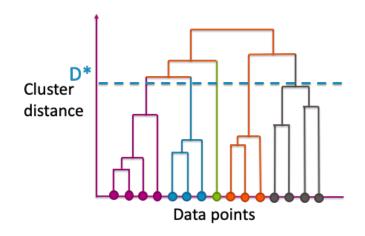

sli.do #cs416

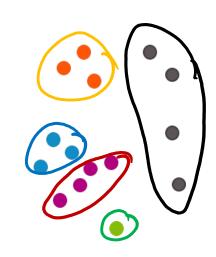

How many clusters would we have if we use this threshold?

Cut Dendrogram

Every branch that crosses D^* becomes its own cluster

Choices to Make

For agglomerative clustering, you need to make the following choices:

Distance metric $d(x_i, x_j)$

Linkage function

- Single Linkage:

$$D(C_1, C_2) = \min_{x_i \in C_1, x_j \in C_2} d(x_i, x_j)$$

- Complete Linkage:

$$D(C_1, C_2) = \max_{x_i \in C_1, x_j \in C_2} d(x_i, x_j)$$

Centroid Linkage

$$D(C_1, C_2) = d(\mu_1, \mu_2)$$

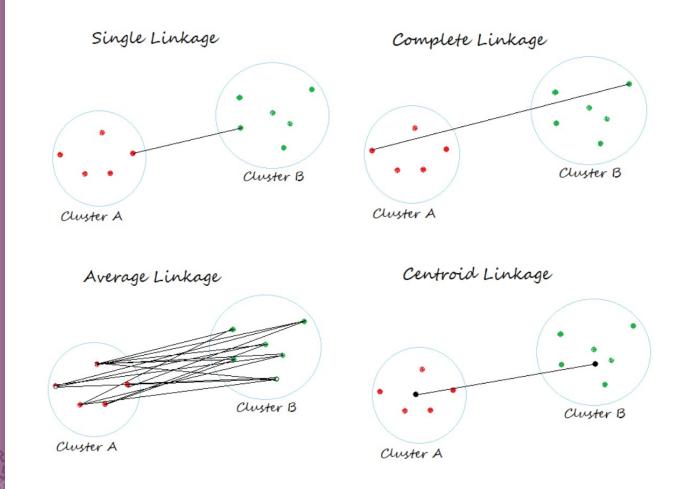

Others

Cluster distance Data points

Where and how to cut dendrogram

Linkage <u>Fu</u>nctions

Practical Notes

For visualization, generally a smaller # of clusters is better

For tasks like outlier detection, cut based on:

Distance threshold

Or some other metric that tries to measure how big the distance increased after a merge

No matter what metric or what threshold you use, no method is "incorrect". Some are just more useful than others.

Computational Cost of Agglomerative Clustering

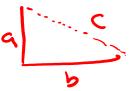

Computing all pairs of distances is pretty expensive!

A simple implementation takes $O(n^2 \log(n))$

Can be much implemented more cleverly by taking advantage of the **triangle inequality**

"Any side of a triangle must be less than the sum of its sides"

Best known algorithm is $\mathcal{O}(n^2)$

k-means vs. Agglomerative Clustering

K-means is more efficient on big data than hierarchical clustering.

Initialization changes results in k-means, not in agglomerative clustering has reproducible results.

K-means works well only for hyper-spherical clusters, agglomerative clustering can handle more complex cluster shapes.

K-means requires selecting a number of clusters beforehand. In agglomerative clustering, you can decide on the number of clusters afterwards using the dendrogram.

Concept Inventory

This week we want to practice recalling vocabulary. Spend 10 minutes trying to write down all the terms for concepts we have learned in this class and try to bucket them into the following categories.

Regression

Classification

Deep Learning

Document Retrieval

Misc – For things that fit in multiple places or none of the above

You don't need to define/explain the terms for this exercise, but you should know what they are!

Try to do this for at least 5 minutes from recall before looking at your notes!
