Pre-Lecture Video
Imagine I made a “Dummy Classifier” for detecting spam
The classifier ignores the input, and always predicts spam.
This actually results in 90% accuracy! Why?
- Most emails are spam...

This is called the **majority class classifier**.

A classifier as simple as the majority class classifier can have a high accuracy if there is a **class imbalance**.

A class imbalance is when one class appears much more frequently than another in the dataset

This might suggest that accuracy isn’t enough to tell us if a model is a good model.
Always digging in and ask critical questions of your accuracy.

Is there a class imbalance?

How does it compare to a baseline approach?
- Random guessing
- Majority class
- ...

Most important: What does my application need?
- What’s good enough for user experience?
- What is the impact of a mistake we make?
For binary classification, there are only two types of mistakes

\[ \hat{y} = +1, \ y = -1 \]

\[ \hat{y} = -1, \ y = +1 \]

Generally we make a **confusion matrix** to understand mistakes.

```
<table>
<thead>
<tr>
<th>Predicted Label</th>
<th>True Label</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>+</td>
</tr>
<tr>
<td>True Positive (TP)</td>
<td></td>
</tr>
<tr>
<td>False Negative (FN)</td>
<td></td>
</tr>
<tr>
<td>False Positive (FP)</td>
<td></td>
</tr>
<tr>
<td>True Negative (TN)</td>
<td></td>
</tr>
</tbody>
</table>
```

Confusion Matrix
Binary Classification Measures

Notation

\[ C_{TP} = \#TP, \quad C_{FP} = \#FP, \quad C_{TN} = \#TN, \quad C_{FN} = \#FN \]
\[ N = C_{TP} + C_{FP} + C_{TN} + C_{FN} \]
\[ N_p = C_{TP} + C_{FN}, \quad N_N = C_{FP} + C_{TN} \]

Error Rate

\[ \frac{C_{FP} + C_{FN}}{N} \]

Accuracy Rate

\[ \frac{C_{TP} + C_{TN}}{N} \]

False Positive rate (FPR)

\[ \frac{C_{FP}}{N_N} \]

False Negative Rate (FNR)

\[ \frac{C_{FN}}{N_p} \]

True Positive Rate or Recall

\[ \frac{T_P}{N_p} \]

Precision

\[ \frac{T_P}{C_{TP} + C_{FP}} \]

F1-Score

\[ \frac{2 \cdot Precision \cdot Recall}{Precision + Recall} \]

See more!
What if I never want to make a false positive prediction?

What if I never want to make a false negative prediction?

One way to control for our application is to change the scoring threshold. (Could also change intercept!)

If $Score(x) > \alpha$:
- Predict $\hat{y} = +1$

Else:
- Predict $\hat{y} = -1$
ROC Curve

What happens to our TPR and FPR as we increase the threshold?
Often with binary classification, we treat the positive label as being the more important of the two. We then often then focus on these metrics:

**Precision:** Of the ones I predicted positive, how many of them were actually positive?

**Recall:** Of all the things that are truly positive, how many of them did I correctly predict as positive?
What fraction of the examples I predicted positive were correct?

Sentences predicted to be positive:

\[ \hat{y}_i = +1 \]

<table>
<thead>
<tr>
<th>Sentence</th>
<th>Correct?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Easily best sushi in Seattle.</td>
<td>✓</td>
</tr>
<tr>
<td>The seaweed salad was just OK, vegetable salad was just ordinary.</td>
<td>✘</td>
</tr>
<tr>
<td>I like the interior decoration and the blackboard menu on the wall.</td>
<td>✓</td>
</tr>
<tr>
<td>The service is somewhat hectic.</td>
<td>✘</td>
</tr>
<tr>
<td>The sushi was amazing, and the rice is just outstanding.</td>
<td>✓</td>
</tr>
<tr>
<td>All the sushi was delicious.</td>
<td>✓</td>
</tr>
</tbody>
</table>

Only 4 out of 6 sentences predicted to be positive are actually positive.

\[
\text{precision} = \frac{C_{TP}}{C_{TP} + C_{FP}}
\]
Recall

Of the truly positive examples, how many were predicted positive?

\[
\text{recall} = \frac{C_{TP}}{\hat{Y}} = \frac{C_{TP}}{C_{TP} + \bar{C}_{TP}}
\]

Sentences from all reviews for my restaurant:

- Easily best sushi in Seattle.
- The seaweed salad was just OK, vegetable salad was just ordinary.
- I like the interior decoration and the blackboard menu on the wall.
- The service is somewhat hectic.
- The sushi was amazing, and the rice is just outstanding.
- All the sushi was delicious.
- The seaweed salad was just OK, vegetable salad was just ordinary.
- My wife tried their ramen and it was delicious.
- The service is somewhat hectic.
- My wife tried their ramen and it was pretty forgettable.
- The service was perfect.

Classifier MODEL

Predicted positive \( \hat{y}_i = +1 \)

- Easily best sushi in Seattle.
- The seaweed salad was just OK, vegetable salad was just ordinary.
- I like the interior decoration and the blackboard menu on the wall.
- The service is somewhat hectic.
- The sushi was amazing, and the rice is just outstanding.
- All the sushi was delicious.

Predicted negative \( \hat{y}_i = -1 \)

- The seaweed salad was just OK, vegetable salad was just ordinary.
- My wife tried their ramen and it was delicious.
- The service is somewhat hectic.
- My wife tried their ramen and it was pretty forgettable.
- The service was perfect.

True positive sentences: \( y_i = +1 \)
Precision & Recall

An optimistic model will predict almost everything as positive
High recall, low precision

A pessimistic model will predict almost everything as negative
High precision, low recall

Want to find many positive sentences, but minimize risk of incorrect predictions!!

PESSIMISTIC MODEL
Finds few positive sentences, but includes no false positives

OPTIMISTIC MODEL
Finds all positive sentences, but includes many false positives
Controlling Precision/Recall

Depending on your application, precision or recall might be more important. Ideally you will have high values for both, but generally increasing recall will decrease precision and vice versa.

For logistic regression, we can control for how optimistic the model is by changing the threshold for positive classification

Before
\[ \hat{y}_i = +1 \text{ if } \hat{P}(y = +1|x_i) > 0.5 \text{ else } \hat{y}_i = -1 \]

Now
\[ \hat{y}_i = +1 \text{ if } \hat{P}(y = +1|x_i) > t \text{ else } \hat{y}_i = -1 \]
Precision-Recall Curve
Can try every threshold to get a curve like below
Sometimes, Classifier B is strictly better than Classifier A
Most times, the classifiers are incomparable.
Often come up with a single number to describe it
F1-score, AUC, etc.
Remember, what your application needs is most important

Also common to use precision at k
If you show the top k most likely positive examples, how many of them are true positives

<table>

Consider you had some time to read a book and wanted to find other books similar to that one.

If we wanted to write a system to recommend books

- How do we measure similarity?
- How do we search over books?
- How do we measure accuracy?

**Big Idea:** Define an embedding and a similarity metric for the books, and find the "nearest neighbor" to some query book.
Nearest Neighbors
1-Nearest Neighbor

**Input**
- $x_q$: Query example (e.g. my book)
- $x_1, \ldots, x_n$: Corpus of documents (e.g. Amazon books)

**Output**
The document in corpus that is most similar to $x_q$

$$x^{NN} = \arg \min_{x_i \in [x_1, \ldots, x_n]} distance(x_q, x_i)$$

It's very critical to properly define how we represent each document $x_i$ and the similarity metric $distance$! Different definitions will lead to very different results.
How long does it take to find the 1-NN? About \( n \) operations

\[ \text{Input: } x_q \]
\[ x_{NN} = \emptyset \]
\[ nn\_dist = \infty \]

for \( x_i \in [x_1, \ldots, x_n] \):
\[ \text{dist} = \text{distance}(x_q, x_i) \]
if \( \text{dist} < nn\_dist \):
\[ x_{NN} = x_i \]
\[ nn\_dist = \text{dist} \]

\[ \text{Output: } x_{NN} \]
**k-Nearest Neighbors**

**Input**
- $x_q$: Query example (e.g. my book)
- $x_1, \ldots, x_n$: Corpus of documents (e.g. Amazon books)

**Output**
- List of $k$ documents most similar to $x_q$

**Formally**
Nearest Neighbors

Same idea as 1-NN algorithm, but maintain list of k-NN

**Input:** \( x_q \)

\[ X^{k\text{NN}} = [x_1, \ldots, x_k] \]

\[ \text{nn}_\text{dists} = [\text{dist}(x_1, x_q), \text{dist}(x_2, x_q), \ldots, \text{dist}(x_k, x_q)] \]

for \( x_i \in [x_{k+1}, \ldots, x_n] \):

\[ \text{dist} = \text{distance}(x_q, x_i) \]

if \( \text{dist} < \text{max}(\text{nn}_\text{dists}) \):

remove largest \( \text{dist} \) from \( X^{k\text{NN}} \) and \( \text{nn}_\text{dists} \)

add \( x_i \) to \( X^{k\text{NN}} \) and distance \( (x_q, x_i) \) to \( \text{nn}_\text{dists} \)

**Output:** \( X^{k\text{NN}} \)
k-Nearest Neighbors

Can be used in many circumstances!

**Retrieval**
Return \( X^{k-\text{NN}} \)

**Regression**
\[
\hat{y}_i = \frac{1}{k} \sum_{j=1}^{k} x_{N_N_j}
\]

**Classification**
\[
\hat{y}_i = \text{majority\_class}(X^{k-\text{NN}})
\]
In the regression/classification settings, what is the relationship between k for k-NN and the bias/variance of the model? Each option completes the sentence “As k increases ...”

- Bias increases, Variance increases
- Bias decreases, Variance increases
- Bias increases, Variance decreases
- Bias decreases, Variance decreases
Brain Break

1:00
Embeddings
While the formalization of these algorithms can be a bit tedious, the intuition is fairly simple. Find the 1 or k nearest neighbors to a given document and return those as the answer.

This intuition relies on answering two important questions

- How do we represent the documents \( x_i \)?
- How do we measure the distance \( \text{distance}(x_q, x_i) \)?
Like our previous ML algorithms, we will want to make a vector out of the document to represent it as a point in space.

Simplest representation is the **bag-of-words** representation.

Each document will become a $W$ dimension vector where $W$ is the number of words in the entire corpus of documents.

The value of $x_i[j]$ will be the number of times word $j$ appears in document $i$.

This ignores order of words in the document, just the counts.

$I$ really really like dogs

$[! \ 2 \ ! \ 1 \ 0]$

$[0 \ 0 \ 0 \ 0 \ 1 \ 3 \ W]$
Bag of Words

Pros
Very simple to describe
Very simple to compute

Cons
Common words like “the” and “a” dominate counts of uncommon words
Often it’s the uncommon words that uniquely define a doc.
**TF-IDF**

**Goal:** Emphasize important words
- Appear frequently in the document (common locally)
- Appears rarely in the corpus (rare globally)

**Term frequency =**

**Inverse doc freq. =**

Do a pair-wise multiplication to compute the TF-IDF for each word.

Words that appear in every document will have a small IDF making the TF-IDF small!
What is the $TF-IDF$ of "rain" with the following documents (assume standard pre-processing):

Doc 1: It is going to rain today.
Doc 2: Today I am not going outside.
Doc 3: I am going to watch the season premiere.

$TF = \frac{freq \text{("rain")}}{\text{num words}}$

$IDF = \log \left( \frac{\text{num docs}}{\text{docs containing "rain"}} \right)$

$TF-IDF = \frac{TF \times IDF}{\text{num words}}$
Distance
Now we will define what similarity/distance means.

Want to define how “close” two vectors are. A smaller value for distance means they are closer, a large value for distance means they are farther away.

The simplest way to define distance between vectors is the **Euclidean distance**

$$distance(x_i, x_q) = \left\| x_i - x_q \right\|_2 = \sqrt{\sum_{j=1}^{D} (x_i[j] - x_q[j])^2}$$
Another common choice of distance is the Manhattan Distance

\[ \text{distance}(x_i, x_q) = \left\| x_i - x_q \right\|_1 = \sum_{j=1}^{D} |x_i[j] - x_q[j]| \]
Weighted Distances

Some features vary more than others or are measured in different units. We can weight different dimensions differently to make the distance metric more reasonable.

Weighted Euclidean distance

For feature $j$:

$$a_j = \frac{1}{\max(x[j]) - \min(x[j])}$$

Weighted Euclidean distance

$$\text{distance}(x_i, x_q) = \sqrt{\sum_{j=1}^{D} a_j^2 (x_i[j] - x_q[j])^2}$$
Another natural similarity measure would use

$$x_i^T x_q = \sum_{j=1}^{D} x_i[j] x_q[j]$$

Notice this is a measure of similarity, not distance
This means a bigger number is better
Cosine Similarity

Should we normalize the vectors before finding the similarity?

\[
similarity = \frac{x_i^T x_q}{\|x_i\|_2 \|x_q\|_2} = \cos(\theta)
\]

Note:

- Not a true distance metric
- Efficient for sparse vectors!
Cosine Similarity

In general

\[-1 \leq \text{cosine similarity} \leq 1\]

For positive features (like TF-IDF)

\[0 \leq \text{cosine similarity} \leq 1\]

Define

\[\text{distance} = 1 - \text{similarity}\]
To Normalize or Not To Normalize?

Not normalized

Similarity = 13

1 0 0 0 5 3 0 0 1 0 0 0 0
3 1 0 0 2 0 0 1 0 1 0 0 0

Similarity = 52

2 0 0 0 1 0 6 0 0 2 0 0 0 0
6 2 0 0 4 0 0 2 0 2 0 0 0
To Normalize or Not To Normalize?

<p>| | | | | | | | | | |</p>
<table>
<thead>

<td>1 / 4</td>
<td>0</td>
<td>1 / 2</td>
<td>1</td>
<td>0</td>
<td>1 / 4</td>
<td>0</td>
</tr>
</tbody>
</table>

Normalized

Similarity = 13/24

Similarity = 13/24
To Normalize or Not To Normalize?

Normalization is not desired when comparing documents of different sizes since it ignores length.

Normalizing can make dissimilar objects appear more similar.

Common compromise: Just cap maximum word counts.

In practice, can use multiple distance metrics and combine them using some defined weights.
For the given documents, what are their Euclidean Distance and Cosine Similarity?

Assume we are using a bag of words representation.

Document 1: “I really like dogs”

Document 2: “dogs are really really really awesome”

Steps:

- Write out bag of words vectors
- Compute Euclidean distance
- Compute Cosine similarity
I really like dogs. Dogs are really really cool.

\[ ED = \sqrt{(1)^2 + (-1)^2 + 1^2 + 0^2 + 1^2 + 0^2} = \sqrt{5} \]

\[ \cos \phi = \frac{0 + 2 + 0 + 1 + 0 + 0}{\sqrt{4} \cdot \sqrt{7}} = \frac{1 - \frac{3}{\sqrt{28}}}{2} \]
Jaccard Similarity

Yet another popular similarity measure for text documents. Compare the overlap of words appearing in both documents.

\[ J(Doc_i, Doc_j) = \frac{|Doc_i \cap Doc_j|}{|Doc_i \cup Doc_j|} \]

Where \( Doc_i \) and \( Doc_j \) are sets of words in each doc.

Source: Uniqtech - Medium
Recap

**Theme:** Use nearest neighbors to recommend documents.

**Ideas:**

- Precision and Recall Curves
- Implement a nearest neighbor algorithm
- Compare and contrast different document representations
  - Emphasize important words with TF-IDF
- Compare and contrast different measurements of similarity
  - Euclidean and weighted Euclidean
  - Cosine similarity and inner-product similarity
